A THEOREM ON HAMILTONIAN LINE GRAPHS

Ladislav NEBESKÝ, Praha

Abstract: In this paper, the following theorem is proved: Let  $G$  be a graph with at least five vertices and  $\bar{G}$  be the complement of  $G$ ; then for at least one graph  $G'$  of the graphs  $G$  and  $\bar{G}$ ,  $G'$  is connected and the line graph of  $G'$  is hamiltonian.

Key words: hamiltonian graphs; line graphs; the complement of a graph

AMS, Primary: 05C99

Ref. Ž. 8.83

-----

In [5] Harary and Nash-Williams raised the problem of characterizing those graphs the line graph of which is hamiltonian. The present paper is a contribution to this topic.

We shall say that a graph  $G_1$  is an LH-subgraph of a graph  $G_0$  if (i)  $G_1$  is a subgraph of  $G_0$ , (ii)  $G_1$  is either trivial or eulerian, and (iii) for each edge  $x = uv$  of  $G_0$ , at least one of the vertices  $u$  and  $v$  belongs to  $G_1$ . (For the terms of the theory of graphs which are not defined here, see Behzad and Chartrand [1].)

Lemma. Let  $G$  be a connected graph with at least three edges. Then the line graph  $L(G)$  of  $G$  is hamiltonian if and only if  $G$  contains an LH-subgraph.

This lemma directly follows from Proposition 8 in [5]. (Note that for  $G = K(1, 2)$  this proposition does not hold.)

The path  $P_4$ , which is self-complementary, is the only graph  $G$  with four vertices such that (i)  $G$  and the complement  $\bar{G}$  of  $G$  are connected, and (ii) neither  $L(G)$  nor  $L(\bar{G})$  is hamiltonian.

Theorem. Let  $G$  be a graph with  $n \geq 5$  vertices. Then for at least one graph  $G'$  of the graphs  $G$  and  $\bar{G}$ ,  $G'$  is connected and  $L(G')$  is hamiltonian.

Proof. For  $n = 5$ , the proof of the statement can be obtained by exhaustion (diagrams of all 34 graphs with 5 vertices can be found in Harary [4]). Assume that  $n = m \geq 6$  and that for  $n = m - 1$ , the statement is proved. The case when  $\{G, \bar{G}\} = \{K_n, \bar{K}_n\}$  is obvious. We shall assume that  $G$  contains a vertex  $x$  such that  $1 \leq \deg_G x \leq n - 2$ . Denote  $G_0 = G - x$ . By the induction hypothesis, for at least one graph  $G''$  of the graphs  $G_0$  and  $\bar{G}_0$ ,  $G''$  is connected and  $L(G'')$  is hamiltonian. Without loss of generality we assume that  $G'' = G_0$ . As  $G_0$  has at least  $n - 2 \geq 4$  edges, then  $G_0$  contains an LH-subgraph. Obviously,  $G$  is connected. We shall assume that  $L(G)$  is not hamiltonian. Let  $G_1$  be an LH-subgraph of  $G_0$  with the maximum number of vertices.

I) Let  $G_1$  be trivial. Then  $G_0 = K(1, n - 2)$ . As  $L(G)$  is not hamiltonian,  $\bar{G}$  is connected and  $L(G)$  is hamiltonian.

II) Let  $G_1$  be nontrivial. By  $V_0$  and  $V_1$  we denote the vertex set of  $G_0$  and  $G_1$ , respectively. By  $E$  and  $\bar{E}$  we denote the edge set of  $G$  and  $\bar{G}$ , respectively. We denote  $V_2 = V_0 - V_1$ ; by  $m$  we denote the number of

vertices of  $V_2$ . As  $L(G)$  is not hamiltonian, there exists  $ab \in E$  such that  $ab \in E$ . Obviously, the complete graph with the vertex set  $V_2$  is a subgraph of  $\bar{G}$ . If there exists  $w_0 \in V_1$  such that  $kw_0, bw_0 \in E$ , then  $G$  contains an LH-subgraph, which is a contradiction. Thus for each vertex  $v \in V_1$ , either  $kv \in \bar{E}$  or  $bv \in \bar{E}$ . Let  $w_1, w_2 \in V_1$  such that  $w_1w_2 \in E$ . As  $G_1$  is an LH-subgraph of  $G_0$  with the maximum number of vertices and  $G$  contains no LH-subgraph, we can easily prove that either  $kw_1, bw_1 \in \bar{E}$  or  $kw_2, bw_2 \in \bar{E}$ . As  $G_1$  contains a cycle, there exist distinct vertices  $t, u \in V_1$  such that  $kt, bt, ku, bu \in \bar{E}$ .

It is easy to see that  $\bar{G}$  is connected. We shall construct an LH-subgraph of  $\bar{G}$ . Let  $F$  denote the subgraph of  $\bar{G}$  induced by  $V_1$ . Let  $x = v_1v_2$  be an edge of  $F$ ; by  $A(x)$  we denote a set  $\{v_1v_2, v_1v'_1, v_2v'_2\}$  where (i)  $v'_1, v'_2 \in \{k, b\}$ , (ii)  $v_1v'_1, v_2v'_2 \in \bar{E}$ , and (iii) if there exists  $v' \in \{k, b\}$  such that  $v_1v', v_2v' \in E$ , then  $v'_1 = v'_2$ . Consider a maximum matching  $M$  in the graph  $F - t - u$ . By  $A$  we denote the set  $\bigcup_{x \in M} A(x)$ . Let  $j$  denote the number of those  $x \in M$  that there exists an  $k - b$  path of  $\bar{G}$  induced by  $A(x)$ . Let  $v_0$  be a vertex of  $F$  and  $Y$  be a subset of  $\bar{E}$ ; by  $D_{v_0}^Y$  we denote the set of those vertices of  $V_1$  which are adjacent to  $v_0$  in  $F$  and incident with no edge of  $Y$ . If  $j$  is even, then by  $B$  we denote the set  $A \cup \{kt, bt, ku, bu\}$ . Let  $j$  be odd. If  $D_{v_0}^A - \{t\} = \emptyset$ , then by  $B$  we denote the set  $A \cup \{kt, bt\}$ . If  $D_{v_0}^A - \{t\} \neq \emptyset$ , then by  $B$

we denote a set  $A \cup \{nt, st\} \cup A(\mu, \mu')$ , where  $\mu'$  is a vertex of  $D_\mu^A - \{t\}$ . If  $m = 1$ , then by  $Z$  we denote the set  $B$ . If  $m \geq 3$ , then by  $Z$  we denote a set  $B \cup Z^*$ , where  $Z^*$  is the edge set of a cycle with the vertex set  $V_2$ . Let  $m = 2$  and  $s'$  be the only vertex of  $V_2$  different from  $s$ . If each vertex  $w' \in V_1$  adjacent to  $s'$  in  $\bar{G}$  is incident with an edge of  $B$ , then by  $Z$  we denote the set  $B$ . Let there exist  $w' \in V_1$  such that  $s'w' \in \bar{E}$  and  $w'$  is incident with no edge of  $B$ . If  $sw' \in \bar{E}$ , then by  $Z$  we denote  $B \cup \{ss', sw', s'w'\}$ . Let  $sw' \notin \bar{E}$ . Then  $kw' \in \bar{E}$ . If  $D_t^B = \emptyset$ , then by  $Z$  we denote  $(B - \{nt, st\}) \cup \{ss', s'w', kw'\}$ ; if  $w' \in D_t^B$ , then by  $Z$  we denote  $(B - \{st\}) \cup \{ss', s'w', tw'\}$ ; if  $D_t^B \neq \emptyset$  and  $w' \notin D_t^B$ , then by  $Z$  we denote  $(B - \{nt, st\}) \cup \{ss', s'w', kw'\} \cup A(t, t')$ , where  $t'$  is a vertex of  $D_t^B$ .

Now, let  $H$  denote the subgraph of  $G$  induced by  $Z$ . It is easy to see that  $H$  is an LH-subgraph of  $\bar{G}$ . Thus  $L(\bar{G})$  is hamiltonian and the proof is complete.

Corollary. Let  $G$  be a nontrivial graph. Then for at least one graph  $G'$  of the graphs  $G$  and  $\bar{G}$ ,  $G'$  is connected and  $L(G')$  contains a hamiltonian path.

Remark. It is possible to ask for connections between the present theorem (and its proof) and sufficient conditions for a graph to be hamiltonian which depend on properties of the degree sequence (as in [4], pp. 66-68, [1, pp. 131-135], and the most generally in Chvátal [2]), or on the other quantitative indices (Chvátal and Erdős [3]). The following example

gives a partial answer to the problem in question. Let  $n \geq 12$  and  $G$  be the graph which we obtain from the path  $P_3$  and the complement  $\bar{C}_{n-2}$  of the cycle with  $n-2$  vertices in such a way that we identify one vertex of  $\bar{C}_{n-2}$  with one end-vertex of  $P_3$ . Obviously,  $L(G)$  is not hamiltonian. Let  $u$  denote the only end-vertex of  $G$ ; it is easy to see that  $L(G-u)$  is hamiltonian. The graph  $L(\bar{G})$  has  $3n-7$  vertices, the maximum degree  $n$ , the connectivity  $5$ , and the independence number  $\lfloor (n-1)/2 \rfloor$ . The graph  $L(\bar{G})$  is, of course, hamiltonian but its degree sequence does not fulfil the condition of the first statement of Theorem 1 in [2], and the relation between its connectivity and its independence number does not fulfil the condition of Theorem 1 in [3].
