ANNOUNCEMENTS OF NEW RESULTS

SUR LES SOLUTIONS PERIODIQUES DES EQUATIONS PARABOLIQUES DU DEUXIEME ORDRE AVEC LES COEFFICIENTS DISCONTINUS

L. Herrmann (MÚ ČSAV, Žitná 25, 11567 Praha 1, Československo), received 6.11. 1980

On suppose que

- (1) $\Omega \subset \mathbb{R}^n$ est un ouvert borné et convexe avec la frontière $\partial\Omega$ assez régulière,
- (2) $\{a_{jk}(t,x)\}_{j,k=1}^n$ est une matrice des fonctions de $L_\infty(Q)$ ($Q = \mathbb{R} \times \Omega$) ω -périodiques par rapport à t qui est symétrique et uniformément (pour presque tout $(t,x) \in Q$) positif définitive.

On considère le problème

$$\begin{cases} Lu = u_t(t,x) - \sum_{j,k=1}^n (a_{jk}(t,x)u_{x_k}(t,x))_{x_j} = g(t,x), \\ (t,x) \in Q, \quad u \in U \end{cases}$$

où $U = H_\omega^{1,2}(Q) \cap H_\omega^1(Q)$ et $g \in L_{2,\omega}(Q)$.

Nous obtenons l'existence et l'unicité de la solution en suivant presque textuellement Campanato [1]. Il suffit de se rendre compte de deux faits:

- a) l'opérateur $\frac{\partial}{\partial t} - \Delta$ est un isomorphisme topologique de U sur $L_{2,\omega}(Q)$ (cf. Vejvoda et al. [2]),
- b) $\int_0^\omega \int_Q u_t \Delta u \, dx dt = 0$ pour tout $u \in U$.

Théorème. On suppose que (1) and (2) ont lieu. On suppose en outre:

- (3) si l'on désigne par $\mu_j(t,x)$ ($j = 1, \dots, n$) les valeurs propres de la matrice $\{a_{jk}(t,x)\}_{j,k=1}^n$, il existe alors une constante $K \in [0,1)$ de sorte que pour presque tout $(t,x) \in Q$ on ait

$$\frac{\sum_j (\mu_j)^2}{\sum_j \mu_j^2} \geq n - K^2,$$

- (4) il existe deux constantes positives A et B telles que $0 < A \leq \sum_j (\mu_j(t,x))^2 \leq B$ (p.p. dans Q) et $\frac{2A}{A+B} > K$.

Alors l'opérateur L est un isomorphisme topologique de U sur $L_{2,\omega}(Q)$.

ON LENGTHS OF CLOSED GEODETICS

J. Souček (MÚ ČSAV, Žitná 25, 11567 Praha 1, Československo),
received 10.11. 1980

Theorem: Let M be a compact real-analytic Riemannian manifold. Denote by \mathcal{L} the set of lengths of all closed geodesics on M . Then \mathcal{L} is the discrete subset of $[0, +\infty)$, i.e. the set $\mathcal{L} \cap [0, c)$ is finite for all $c > 0$.

Remark. The real-analytic Riemannian manifold is defined as a differentiable manifold, which can be covered by charts such that all transition functions are real-analytic and the metric, expressed in any chart of this cover, is real-analytic, too.

Outline of the proof. The energy functional E can be shown to be analytic in a neighborhood of a geodesic c in the space $H^1(S, M)$ of all curves (see [1]). It suffices to use the methods of [2, Chap. IV, App. VI] in local coordinates. If we use so called infinite-dimensional Morse-Sard theorem [2, Chap. IV], we can show that in a neighborhood of the geodesic c there is only one critical level of the functional E . The Fredholm condition, needed in the proof of this fact, follows from [1, 2.4.2]. Then it is sufficient to use the Palais-Smale condition [1, 1.4.7] and the relation between the length and energy of geodesics.

Detailed proof will be published elsewhere.
