SUBDIRECTLY IRREDUCIBLE GROUPOIDS IN SOME VARIETIES  
J. PŁONKA

**Abstract:** In one special variety of groupoids we study free groupoids, subdirectly irreducible groupoids and the lattice of subvarieties.

**Key words:** Groupoid, subdirectly irreducible groupoid, variety.

**Classification:** 08A30

---

0. In this paper we consider only varieties of groupoids i.e. varieties of type (2) with the fundamental operation  $x \cdot y$  and we accept the terminology from [2]. In [3] two varieties  $\Sigma_2$  and  $\Sigma_3$  of groupoids were considered where  $\Sigma_2$  was defined by the identities

- (1)  $x \cdot x = x$
- (2)  $(x \cdot y) \cdot z = (x \cdot z) \cdot y$
- (3)  $x \cdot (y \cdot z) = x \cdot y$
- (4)  $(x \cdot y) \cdot y = x \cdot y$

and  $\Sigma_3$  was defined by (1)-(3) and

- (4')  $(x \cdot y) \cdot y = x$  (see also [2], pp. 394-395).

In [3] it was shown that:

If a groupoid  $\mathcal{G}$  belongs to  $\Sigma_2$  or  $\Sigma_3$  and the operation  $x \cdot y$  depends on both variables in  $\mathcal{G}$  then there exist in  $\mathcal{G}$  exactly  $n$   $n$ -ary polynomials depending on  $n$  variables.

In [4] all subdirectly irreducible groupoids in  $\Sigma_2$  and  $\Sigma_3$  were found.

In this paper we study the join  $\Sigma_2 \vee \Sigma_3$ . In Section 1 we prove that  $\Sigma_2 \vee \Sigma_3$  is defined by the identities (1)-(3) and the identity

$$(5) \quad ((x \cdot y) \cdot y) \cdot y = x \cdot y.$$

We show that the only subvarieties of  $\Sigma_2 \vee \Sigma_3$  are  $\Sigma_2$ ,  $\Sigma_3$ , the trivial variety  $\mathbf{T}$  i. e. the variety defined by the identity  $x=y$  and the variety  $\Sigma_0$  defined by the identity  $x \cdot y = x$  (see Theorem 1).

In Theorem 2, Section 1 we describe the free algebras in  $\Sigma_2 \vee \Sigma_3$ . In Section 2 we find all subdirectly irreducible groupoids in  $\Sigma_2 \vee \Sigma_3$ .

For a variety  $K$  of type (2) we denote by  $E(K)$  the set of all identities of type (2) satisfied in all groupoids from  $K$ . A term  $\varphi$  of type (2) constructed by means of the operation  $\cdot$  will be called a multiplication term. We shall use the notation  $(\underbrace{\dots(x \cdot y) \cdot y \dots}_{n \text{ times}}) \cdot y = x \cdot y^n$

1. Example 1. Let  $X$  be a set such that  $|X| > 1$ . Denote  $B = \{ \langle a, A \rangle : a \in A \subseteq X \}$ . Consider a groupoid  $\mathcal{G} = (B, \cdot)$  where  $\langle a, A \rangle \cdot \langle a', A' \rangle = \langle a, A \cup \{a'\} \rangle$ . Then  $\mathcal{G}$  satisfies (1)-(4) so  $\mathcal{G} \in \Sigma_2$ , but  $\mathcal{G}$  does not satisfy (4').

Example 2. Let  $Z_4 = (\{0, 1, 2, 3\}; +)$  be a cyclic group with addition modulo 4. Consider a groupoid  $\mathcal{G} = (\{0, 1, 2, 3\}; \cdot)$  where  $x \cdot y = 3x + 2y$ . Then  $\mathcal{G}$  satisfies (1)-(3) and (4') so  $\mathcal{G} \in \Sigma_3$ , but it does not satisfy (4).

Let  $\Sigma$  be the variety of groupoids defined by (1)-(3) and

(5). Let  $\alpha$  be an ordinal. A multiplication term  $\varphi$  on variables  $x_0, x_1, \dots, x_\beta, \dots$  ( $\beta < \alpha$ ) will be called a reduced iteration if  $\varphi$  is of the form

(6)  $x_{i_1} \cdot x_{i_2}^{k_2} \cdot \dots \cdot x_{i_n}^{k_n}$  where all variables  $x_{i_1}, \dots, x_{i_n}$  are different,  $i_2 < i_3 < \dots < i_n$ ,  $0 < k_j \leq 2$  for  $j=2, \dots, n$ .

Lemma 1. For any multiplication term  $\varphi$  there exists a reduced iteration of the form (6) such that the identity  $\varphi = x_{i_1} \cdot x_{i_2}^{k_2} \cdot \dots \cdot x_{i_n}^{k_n}$  belongs to  $E(\Sigma)$ .

Proof. In fact by (3) we can reduce all open parentheses standing after a variable in  $\varphi$ . Then we get  $\varphi = (\dots(x_{s_1} \cdot x_{s_2}) \dots) x_{s_r}$  belongs to  $E(\Sigma)$ . By (2) the order of variables  $x_{s_2}, \dots, x_{s_r}$  is arbitrary and we get  $\varphi = (\dots(x_{i_1} \cdot x_{i_1}) \dots) \cdot x_{i_1} \cdot x_{i_2} \dots) x_{i_2} \dots) x_{i_n} \dots) \cdot x_{i_n}$  belongs to  $E(\Sigma)$  where  $i_1 = s_1$  and  $i_2 < i_3 < \dots < i_n$ . Now by (1) and (5) we get the statement of the Lemma.

Lemma 2. If two reduced iterations  $x_{i_1} \cdot x_{i_2}^{k_2} \cdot \dots \cdot x_{i_n}^{k_n}$  and  $x_{j_1} \cdot x_{j_2}^{q_2} \cdot \dots \cdot x_{j_m}^{q_m}$  are different then the identities (1)-(3) together with the identity

$$(7) \quad x_{i_1} \cdot x_{i_2}^{k_2} \cdot \dots \cdot x_{i_n}^{k_n} = x_{j_1} \cdot x_{j_2}^{q_2} \cdot \dots \cdot x_{j_m}^{q_m}$$

imply one of the following identities: (4), (4'),  $x \cdot y = x$ .

Proof. If  $i_1 \neq j_1$  then multiplying (7) on left by  $x_{i_1}$  we get by (3)  $x_{i_1} \cdot x_{j_1} = x_{i_1}$ . If  $i_1 = j_1$  but there exists  $i_r$ ,  $r \in \{2, \dots, n\}$  such that  $i_r \notin \{j_2, \dots, j_m\}$  then putting in (7)  $x_{i_1}$  for all variables different from  $x_{i_r}$  we get by (1)-(3)  $x_{i_1} \cdot x_{i_r} = x_{i_1}$  or  $x_{i_1} \cdot (x_{i_r})^2 = x_{i_1}$ . If the variables on both sides of (7) are the same but  $k_r \neq q_r$  for some  $1 < r \leq n$  then putting

$x_{i_1}$  for all variables different from  $x_{i_r}$  we get  $x_{i_1} \cdot x_{i_r} = x_{i_1} \cdot (x_{i_r})^2$ . Thus anyway we get one of the identities from the lemma.

**Theorem 1.** The lattice of subvarieties of  $\Sigma$  consists of the varieties  $T, \Sigma_0, \Sigma_2, \Sigma_3$  and  $\Sigma$  where  $T \subset \Sigma_0, \Sigma_0 \subset \Sigma_2, \Sigma_0 \subset \Sigma_3, \Sigma_2$  and  $\Sigma_3$  are incomparable and  $\Sigma = \Sigma_2 \vee \Sigma_3$ .

**Proof.** The varieties  $\Sigma_2$  and  $\Sigma_3$  are incomparable (see Examples 1 and 2). Obviously any of the varieties  $T, \Sigma_0, \Sigma_2, \Sigma_3$  is a subvariety of  $\Sigma$  since any of the identities  $x=y, x \cdot y = x, (4), (4')$  implies (5). Obviously  $T \subset \Sigma_0, \Sigma_0 \subset \Sigma_2, \Sigma_0 \subset \Sigma_3$ . On the other hand, J. Dudek proved in [1] that  $T$  and  $\Sigma_0$  are the only subvarieties of  $\Sigma_2$  and  $\Sigma_3$  and all are different. Thus to complete the proof it is enough to show that if  $K$  is a proper subvariety of  $\Sigma$  then  $K$  is a subvariety of  $\Sigma_2$  or  $\Sigma_3$ . Let

$$(8) \quad (\varphi = \psi) \in E(K) \setminus E(\Sigma).$$

By Lemma 1,  $\varphi = x_{i_1} \cdot x_{i_2}^{k_2} \dots x_{i_n}^{k_n}$  and  $\psi = x_{j_1} \cdot x_{j_2}^{q_2} \dots x_{j_m}^{q_m}$  so  $\varphi = \psi$  implies (7) where by (8) the sides of (7) are different. Now by Lemma 2,  $K$  is a subvariety of  $\Sigma_2$  or  $\Sigma_3$ .

**Example 3.** In the set  $\{0,1,2\}$  let us define an operation  $\oplus$  putting

$$(9) \quad x \oplus y = \begin{cases} x+y & \text{if } x+y \leq 2 \\ x+y-2 & \text{otherwise} \end{cases}$$

Let us consider a groupoid  $\mathcal{Q} = (\{0,1,2\} \times \{0,1,2\}; \cdot)$  where

$$\langle x_1, y_1 \rangle \cdot \langle x_2, y_2 \rangle = \begin{cases} \langle x_1, y_1 \rangle & \text{if } x_1 = x_2 \\ \langle x_1, y_1 \oplus x_2 \rangle & \text{otherwise.} \end{cases}$$

Then  $\mathcal{Q}$  satisfies (1)-(3) and (5) so  $\mathcal{Q}$  belongs to  $\Sigma$  and  $\mathcal{Q}$  satisfies neither (4) nor (4').

Let  $\alpha$  be an ordinal. If  $a \in \{0,1,2\}^\alpha$  we shall denote by  $a(k)$  the  $k$ 'th coordinate of  $a$ . Let us denote by  $p_k$  the element of  $\{0,1,2\}^\alpha$  for which  $p_k(k) = 1$  and  $p_k(i) = 0$  for  $i \neq k$ . We denote by  $B$  the set of all  $a \in \{0,1,2\}^\alpha$  having a finite number of coordinates different from 0. Finally let  $B_\alpha = \{\langle p_k, a \rangle : k < \alpha, a \in B, a(k) = 0\}$ .

We define a groupoid  $\mathcal{L}_\alpha = (B_\alpha, \cdot)$  where

$$\langle p_k, a \rangle \cdot \langle p_{k_1}, a_1 \rangle = \begin{cases} \langle p_k, a \rangle & \text{if } k = k_1 \\ \langle p_{k_1}, a_1 \rangle & \text{otherwise} \end{cases}$$

where  $a'(i) = a(i) \oplus p_{k_1}(i)$ ;  $\oplus$  is defined by (9).

**Theorem 2.** A free groupoid in the variety  $\Sigma$  with  $\alpha$  free generators is isomorphic to  $\mathcal{L}_\alpha$ .

**Proof.** Let  $F_\alpha$  be the set of all multiplication terms on variables  $x_0, x_1, \dots, x_\beta, \dots, \beta < \alpha$ . Let  $\sim$  be a relation in  $F_\alpha$  defined by the formula  $\varphi \sim \psi \iff (\varphi = \psi) \in E(\Sigma)$ . A free algebra with  $\alpha$  free generators in  $\Sigma$  is isomorphic to the algebra

$\mathcal{F}_\alpha = (\{[\varphi]_\sim\}_{\varphi \in F_\alpha}; \cdot)$ . By Lemma 1 any term  $\varphi$  has a representation in the form  $\varphi = x_{i_1}^{k_1} \cdot x_{i_2}^{k_2} \cdot \dots \cdot x_{i_n}^{k_n}$ . But this representation is unique. In fact if  $\varphi = x_{i_1}^{k_1} \cdot x_{i_2}^{k_2} \cdot \dots \cdot x_{i_n}^{k_n}$  and  $\varphi = x_{j_1}^{q_1} \cdot x_{j_2}^{q_2} \cdot \dots \cdot x_{j_m}^{q_m}$  where the right sides of the last identities are different then by Lemma 2 one of the identities (4), (4') or  $x \cdot y = x$  belongs to  $E(\Sigma)$ , which contradicts Example 3.

Now the mapping  $h$  defined by the formula

$h([\underbrace{x_{i_1} \cdot x_{i_2}^{k_2} \cdot \dots \cdot x_{i_n}^{k_n}}_\sim]) = \langle p_{i_1}, b \rangle$ , where  $b(i_j) = k_j$  for  $2 \leq j \leq n$  and  $b(r) = 0$  for  $r \notin \{i_2, \dots, i_n\}$  - sets up an isomorphism of  $\mathcal{F}_\alpha$  onto  $\mathcal{L}_\alpha$ . In fact  $h$  is 1-1 since the representation from

Lemma 1 is unique and  $h$  is a homomorphism by (1)-(3) and (5).

2. For a class  $K$  of groupoids we shall denote by  $P(K)$ ,  $S(K)$ ,  $H(K)$  and  $I(K)$  the classes of all products, subgroupoids, homomorphic images and isomorphic copies of groupoids from  $K$ , respectively. If  $\{X_i\}_{i \in I}$  is a partition of a set  $X$  we shall denote by  $e(\{X_i\}_{i \in I})$  the equivalence relation induced by this partition.

Let us consider the following 6 groupoids

$$\mathcal{G}_1 = (\{a\}; \cdot).$$

$$\mathcal{G}_2 = (\{a, b\}; \cdot) \text{ where } x \cdot y = x \text{ for any } x, y \in \{a, b\}.$$

$$\mathcal{G}_3 = (\{a, b, \alpha_1\}; \cdot) \text{ where } a \cdot \alpha_1 = b, b \cdot \alpha_1 = a \text{ and } x \cdot y = x \text{ otherwise.}$$

$$\mathcal{G}_4 = (\{a, b, c, \alpha_1\}; \cdot) \text{ where } a \cdot \alpha_1 = b, b \cdot \alpha_1 = a \text{ and } x \cdot y = x \text{ otherwise.}$$

$$\mathcal{G}_5 = (\{a, c, \alpha_2\}; \cdot) \text{ where } a \cdot \alpha_2 = c, \text{ and } x \cdot y = x \text{ otherwise.}$$

$$\mathcal{G}_6 = (\{a, b, c, \alpha_1, \alpha_2\}; \cdot) \text{ where } a \cdot \alpha_1 = b, b \cdot \alpha_1 = a, a \cdot \alpha_2 = \\ = b \cdot \alpha_2 = c \text{ and } x \cdot y = x \text{ otherwise.}$$

It was proved in [4] that

(i) a groupoid  $\mathcal{G}$  belongs to  $\Sigma_2$  and it is subdirectly irreducible iff  $\mathcal{G}$  is isomorphic to one of the groupoids  $\mathcal{G}_1$ ,

$$\mathcal{G}_2, \mathcal{G}_5.$$

(ii) A groupoid  $\mathcal{G}$  belongs to  $\Sigma_3$  and is subdirectly irreducible iff  $\mathcal{G}$  is isomorphic to one of the groupoids  $\mathcal{G}_1, \mathcal{G}_2$ ,

$$\mathcal{G}_3, \mathcal{G}_4.$$

Lemma 3. The groupoid  $\mathcal{G}_6$  belongs to  $\Sigma$ , moreover  $\mathcal{G}_6 \in \text{HSP} \{ \mathcal{G}_3, \mathcal{G}_5 \}$ .

In fact the set  $S = (\{a, b, \alpha_1\} \times \{a, b, \alpha_2\}) \setminus \{ \langle \alpha_1, \alpha_2 \rangle \}$  is a subalgebra of  $\mathcal{G}_3 \times \mathcal{G}_5$ . So the algebra  $\mathcal{A} = (S; \cdot)$  belongs to  $\text{SP} \{ \mathcal{G}_3, \mathcal{G}_5 \}$ . Further, a relation

$$e = e(\{ \langle a, a \rangle \}, \{ \langle b, a \rangle \}, \{ \langle a, c \rangle, \langle b, c \rangle \}, \{ \langle x_1, a \rangle, \langle x_1, c \rangle \}, \{ \langle a, x_2 \rangle, \langle b, x_2 \rangle \} )$$

is a congruence in  $\mathcal{G}^*$ . Finally, the algebra  $\mathcal{G}^*/e$  is isomorphic to  $\mathcal{G}_6$ .

Lemma 4. The groupoid  $\mathcal{G}_6$  is subdirectly irreducible.

*Proof.* It is enough to show that if  $R$  is a congruency in  $\mathcal{G}_6$  such that  $[a]_R \neq [b]_R$  then  $R = \omega$  where  $\omega$  is the diagonal. We shall write  $[x]$  instead of  $[x]_R$ . In fact, let  $c \in [a]$ . Then  $b = a \cdot x_1 R c \cdot x_1 = c R a$ . So  $b R a$  - a contradiction. The same contradiction gives the assumption that  $c \in [b]$ . If  $c \in [x_1]$  then  $a = a \cdot c R a \cdot x_1 = b$  - a contradiction. If  $c \in [x_2]$  then  $a = a \cdot c R a \cdot x_2 = c$  - a contradiction (see the first case). So  $[c] = \{c\}$ . If  $x_1 \in [a]$  then  $b = a \cdot x_1 R a \cdot a = a$  - a contradiction. The same contradiction gives the assumption  $x_1 \in [b]$ . If  $x_1 \in [x_2]$  then  $a = b \cdot x_1 R b \cdot x_2 = c$  - a contradiction. So  $[x_1] = \{x_1\}$ . If  $x_2 \in [a]$  then  $a = a \cdot a R a \cdot x_2 = c$  - a contradiction. Analogously  $x_2 \notin [b]$ . Thus  $R = \omega$ .

Theorem 3. A groupoid  $\mathcal{G}$  belongs to  $\Sigma$  and it is subdirectly irreducible iff  $\mathcal{G}$  is isomorphic to one of the groupoids  $\mathcal{G}_1, \dots, \mathcal{G}_6$ .

*Proof.*  $\Leftarrow$ . For the groupoids  $\mathcal{G}_1, \dots, \mathcal{G}_5$  the statement holds by Theorem 1, (i) and (ii). For the groupoid  $\mathcal{G}_6$  the statement holds by Theorem 1, Lemma 3 and Lemma 4.

Before we prove the necessity we have to show some properties.

Let  $\mathcal{G} = (G, \cdot)$ .

(iii)  $\mathcal{G} \in \Sigma$  iff the following conditions 1<sup>o</sup>, 2<sup>o</sup> and 3<sup>o</sup> are satisfied.

1° There exists a partition  $\{G_i\}_{i \in I}$  of  $G$  such that for any  $i \in I$  the set  $\{h_i^j\}_{j \in I}$  of mappings from  $G_i$  into  $G_i$  is given.

2° The mappings  $h_i^j$  satisfy the following conditions:

$$\begin{aligned} \forall_{i \in I} h_i^i &= \text{id}, \quad \forall_{i, j, s \in I} h_i^j \circ h_i^s = h_i^s \circ h_i^j; \\ \forall_{i, j \in I} h_i^j \circ h_i^j \circ h_i^j &= h_i^j. \end{aligned}$$

3° If  $a \in G_i, b \in G_j$  then  $a \cdot b = h_i^j(a)$ .

The proof is analogous to that of Theorem 3 from [3].

(iv) If  $\mathcal{Q}$  is of the form from (iii),  $a \in G_k$  then for any  $i \in I$  one of the following cases holds.

- (10)  $h_k^i(a) = a$
- (11)  $h_k^i(a) = b \neq a, h_k^i(b) = b$
- (12)  $h_k^i(a) = b, h_k^i(b) = a, a \neq b$
- (13)  $h_k^i(a) = b, h_k^i(b) = c, h_k^i(c) = b, a \neq b, a \neq c, b \neq c$

If  $\{R_s\}_{s \in S}$  is a set of nontrivial congruences in a groupoid  $\mathcal{Q}$  such that  $\bigwedge_{s \in S} R_s = \omega$  then the set  $\{R_s\}_{s \in S}$  will be called a decomposition of  $\mathcal{Q}$ . Obviously, if such a decomposition exists then  $\mathcal{Q}$  is subdirectly reducible.

For a set  $A$  we shall denote by  $D(A)$  the set of all 1-element subsets of  $A$ .

From now on we assume that a groupoid  $\mathcal{Q} = (G; \cdot)$  belongs to  $\bar{\Sigma}$ , is subdirectly irreducible and is of the form from (iii)

Similarly like in [4] (Lemma 1) we can prove

Lemma 5. If for any  $i, j \in I, h_i^j = \text{id}$  then  $\mathcal{Q}$  is isomorphic to  $\mathcal{Q}_1$  or to  $\mathcal{Q}_2$ .

In view of Lemma 5 in the sequel we shall assume that

$$(14) \quad \exists_{i, j \in I} h_i^j \neq \text{id}$$

Let us put  $J = \{j \in I: |G_j| > 1\}$ .

Lemma 6.  $|J| = 1$ .

Proof. By (14) we have  $|J| \geq 1$ . Similarly like in [4] (Lemma 2) we can prove  $|J| \leq 1$ .

By Lemma 6 we can denote by  $k$  the unique element of  $J$ .

Put  $I' = I \setminus \{k\}$ . So for any  $i \in I'$  we have  $|G_i| = 1$ . Thus only mappings  $h_k^j$  for  $j \in I'$  can be different from the identity.

Lemma 7. If  $i, j \in I'$  and  $i \neq j$  then  $h_k^i \neq h_k^j$ .

The proof is analogous to that of Lemma 3 from [4].

Put  $I_0 = \{i \in I' : h_k^i \neq \text{id}\}$ . By (14) we have  $I_0 \neq \emptyset$ .

For any  $i \in I_0$  we define two relations  $R_i$  and  $R^i$  as follows:  
 $a R_i b$  iff  $a=b$  or  $a, b \in G_k$ ,  $b = h_k^i(a)$ , and  $a = h_k^i(b)$ ;  
 $a R^i b$  iff  $a=b$  or  $a, b \in G_k$  and  $h_k^i(a) = h_k^i(b)$ .

Similarly like in [4] we can prove that any of  $R_i$  and  $R^i$  is a congruence of  $\mathcal{G}$ .

Lemma 8. For any  $i \in I_0$  we have  $R_i \neq \omega$  or  $R^i \neq \omega$ .

In fact, since  $|G_j| = 1$  for  $j \in I'$ , so it must exist  $a \in G_k$  such that  $h_k^i(a) \neq a$ . Consequently one of the cases (11), (12) or (13) holds and  $|[a]_{R_i}| > 1$  or  $|[a]_{R^i}| > 1$ .

Lemma 9. For any  $i \in I_0$  we have  $R_i = \omega$  or  $R^i = \omega$ .

In fact,  $R_i \cap R^i = \omega$  since if  $a R_i \cap R^i b$  then  $a = b$  or  $a, b \in G_k$  and  $a = h_k^i(b) = h_k^i(a) = b$ . Thus if both  $R_i$  and  $R^i$  are different from  $\omega$  then  $\{R_i, R^i\}$  is a decomposition of  $\mathcal{G}$  - a contradiction.

Lemma 10. If for some  $i \in I_0$  we have  $R_i = \omega$ , then for  $a \in G_k$  exactly one of the cases (10) or (11) holds. If for some  $i \in I_0$  we have  $R^i = \omega$ , then for  $a \in G_k$  exactly one of the cases

(10) or (12) holds.

In fact, the case (13) is impossible by Lemma 9. If  $R_1 = \omega$  then (12) is impossible. If  $R^1 = \omega$  then (11) is impossible.

We denote  $I_0^2 = \{i \in I_0 : R_1 = \omega\}$ ,  $I_0^3 = \{i \in I_0 : R^1 = \omega\}$ .  
By Lemma 8 and 9 we have  $I_0 = I_0^2 \cup I_0^3$  and  $I_0^2 \cap I_0^3 = \emptyset$ .

Lemma 11. If  $I_0^3 = \emptyset$ , then  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_5$ . If  $I_0^2 = \emptyset$  then  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_3$  or  $\mathcal{G}_4$ .

Proof. If  $I_0^3 = \emptyset$  then by Lemma 10 and (iii) we infer that  $\mathcal{G}$  satisfies (4) and by (i) and (14),  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_5$ .  
If  $I_0^2 = \emptyset$  then by Lemma 10 and (iii) we infer that  $\mathcal{G}$  satisfies (4') and by (ii) and (14),  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_3$  or  $\mathcal{G}_4$ .

Q.E.D.

In view of Lemma 11 from now on we assume that

$$(15) \quad I_0^2 \neq \emptyset \neq I_0^3.$$

$$\text{Denote } R_\cap = \left( \bigcap_{i \in I_0^3} R_1 \right) \cap \left( \bigcap_{i \in I_0^2} R^1 \right).$$

Lemma 12. Any congruence class  $[a]_{R_\cap}$  is either 1-element or is of the form  $[a]_{R_\cap} = \{a, b\}$  where  $a \neq b$ , for any  $i \in I_0^3$  we have  $h_K^1(a) = b$  and  $h_K^1(b) = a$  and for any  $i \in I_0^2$  we have  $h_K^1(a) = h_K^1(b) \notin [a]_{R_\cap}$ .

Proof. For  $i \in I_0^3$  any congruence class  $[a]_{R_1}$  is at most 2-element. So if  $|[a]_{R_\cap}| > 1$  then it must be  $[a]_{R_1} \subseteq [a]_{R_\cap}$ .  
Consequently if  $|[a]_{R_\cap}| > 1$  then  $[a]_{R_\cap} = [a]_{R_1} = \{a, b\}$  where  $a, b \in G_K$ . Moreover for any  $i \in I_0^3$  we have  $h_K^1(a) = b$  and  $h_K^1(b) = a$ . Let  $j \in I_0^2$ ,  $|[a]_{R_\cap}| > 1$  and  $[a]_{R_\cap} = \{a, b\}$ . So

$$(16) \quad h_K^j(a) = h_K^j(b).$$

By (15) and by the first part of the proof there exists  $i \in I_0^3$  such that

$$(17) \quad h_k^1(a) = b \text{ and } h_k^1(b) = a.$$

Let us assume that  $h_k^j(a) \in [a]_{R_\sim}$  and e.g.  $h_k^j(a) = b$ . Then by (16) and (17) we get  $h_k^j h_k^1(a) = b$ ,  $h_k^1 h_k^j(a) = a$ , which contradicts  $2^0$ . Analogously  $h_k^j(a) \neq a$ .

$$\text{Let us denote } R(2) = \{R_i^1\}_{i \in I_0^2} \text{ and } R(3) = \{R_i^1\}_{i \in I_0^3}$$

Lemma 13. The set  $G_k$  contains exactly one 2-element class of the congruence  $R_\sim$  and exactly one 1-element class of the congruence  $R_\sim$ .

Proof. If  $R_\sim = \omega$  then obviously we have a decomposition of  $\mathcal{G}$ , namely  $\{R_i^1\}_{i \in I_0^3} \cup \{R_i^1\}_{i \in I_0^2}$ , since any of these congruences is not trivial. If  $R_\sim \neq \omega$  then by Lemma 12 there exists a 2-element class of the congruence  $R_\sim$ . If there exist two different 2-element classes  $[a]_{R_\sim}$  and  $[a']_{R_\sim}$  included in  $G_k$  then two congruences  $e(\{[a]_{R_\sim}\} \cup D(G \setminus [a]_{R_\sim}))$  and  $e(\{[a']_{R_\sim}\} \cup D(G \setminus [a']_{R_\sim}))$  form a decomposition of  $\mathcal{G}$  - a contradiction. Denote  $Q = [a]_{R_\sim}$ . By Lemma 12 it is easy to check that the relation  $e_Q = e(\{G_k \setminus Q\} \cup D(Q) \cup D(G \setminus G_k))$  is a congruence of  $\mathcal{G}$ . We shall show that

$$|G_k \setminus Q| = 1$$

In fact it cannot be  $G_k \setminus Q = \emptyset$  since  $I_0^2 \neq \emptyset$  and by Lemma 12 it must be for  $j \in I_0^2$ ,  $h_k^j(a) \notin Q$ .

If  $|G_k \setminus Q| > 1$  then  $e_Q$  is nontrivial and  $R(2) \cup R(3) \cup \{e_Q\}$  is a decomposition of  $\mathcal{G}$ .

Proof.  $\Rightarrow$  of Theorem 3. If any  $h_k^1$  is the identity, then by Lemma 5,  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_1$  or  $\mathcal{G}_2$ . Otherwise

by Lemma 6 there exists exactly one  $k \in I$  such that  $|G_k| > 1$  and (14) holds. If  $I_0^3 = \emptyset$ , then by Lemma 11,  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_5$ . If  $I_0^2 = \emptyset$  then by Lemma 11,  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_3$  or  $\mathcal{G}_4$ . If (15) holds then by Lemma 13 we can denote by  $a, b, c$  the elements of  $G_k$  where  $[a]_{R_k} = [b]_{R_k} = \{a, b\}$  and  $[c]_{R_k} = \{c\}$ . By Lemma 12 for any  $i \in I_0^3$  we have  $h_k^i(a) = b$ ,  $h_k^i(b) = a$  and  $h_k^i(c) = c$ . So by Lemma 7 we have  $|I_0^3| = 1$ . Let us put  $I_0^3 = \{i_0\}$  and denote by  $\alpha_1$  the only element of  $G_{i_0}$ . Analogously for any  $j \in I_0^2$  we have by Lemma 12:  $h_k^j(a) = h_k^j(b) = h_k^j(c) = c$ . So by Lemma 7 we have  $|I_0^2| = 1$ . Put  $I_0^2 = \{j_0\}$  and denote by  $\alpha_2$  the only element of  $G_{j_0}$ .

It must be  $I_0 \setminus I_0 = \emptyset$ . In fact, if  $m \in I_0' \setminus I_0$  and  $d$  is the only element of  $G_m$ , then two congruences  $e(\{fd, G \setminus \{fd\}\})$ ,  $e(\{ic, d\}, D(G) \setminus \{ic, d\})$  form a decomposition of  $\mathcal{G}$ . So  $G_k = \{a, b, c\}, G \setminus G_k = \{\alpha_1, \alpha_2\}$  and  $G$  satisfies formulas of multiplication in  $\mathcal{G}_6$ . Thus  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_6$  where the isomorphism is defined by denoting elements of  $G$  in the above way

Q.E.D.

By Birkhoff theorem (see [2], p. 124), we have

Corollary 1. A groupoid  $\mathcal{G}$  belongs to  $\Sigma$  iff  $\mathcal{G}$  is isomorphic to a subdirect product of a family of groupoids  $\mathcal{G}_2 - \mathcal{G}_4$ .

Corollary 2. A groupoid  $\mathcal{G}$  belongs to  $\Sigma$  iff  $\mathcal{G}$  can be embedded into some cartesian power of  $\mathcal{G}_6$ .

In fact, any of the groupoids  $\mathcal{G}_1 - \mathcal{G}_5$  is a subalgebra of  $\mathcal{G}_6$ .

The groupoid  $\mathcal{G}_6$  has 5 elements and generates  $\Sigma$ .

One can ask if there exist groupoids having less elements and generating  $\Sigma$ . The answer is "yes".

Let us consider two groupoids  $\mathcal{G}_7$  and  $\mathcal{G}_8$  defined as follows:

$\mathcal{G}_7 = (\{a, b, c, d\}; \cdot)$  where  $a \cdot d = b$ ,  $b \cdot d = c$ ,  $c \cdot d = b$ , and  $x \cdot y = x$  otherwise.

$\mathcal{G}_8 = (\{a, b, c, d\}; \cdot)$  where  $a \cdot c = a \cdot d = b$ ,  $b \cdot c = b \cdot d = a$ ,  $a \cdot c \cdot b = d \cdot a = d \cdot b$ , and  $x \cdot y = x$  otherwise.

**Theorem 4.**  $\mathcal{G}$  is a 4-element groupoid such that  $\text{HSP}\{\mathcal{G}\} = \Sigma$  iff  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_7$  or  $\mathcal{G}_8$ .

The number 4 is the least number of elements of groupoids generating  $\Sigma$ .

**Proof.** Consider in  $\mathcal{G}_7$  two congruences  $R_1$  and  $R_2$  where  $R_1 = e(\{\{a, c\}, \{b\}, \{d\}\})$ ,  $R_2 = e(\{\{a\}, \{b, c\}, \{d\}\})$ . Then  $\mathcal{G}_7/R_1$  is isomorphic to  $\mathcal{G}_3$  and  $\mathcal{G}_7/R_2$  is isomorphic to  $\mathcal{G}_5$ . But  $R_1 \cap R_2 = \omega$  so  $\mathcal{G}_7$  is isomorphic to a subdirect product of  $\mathcal{G}_3$  and  $\mathcal{G}_5$ . Consequently  $\{\mathcal{G}_3, \mathcal{G}_5\} \subseteq \text{HSP}\{\mathcal{G}_7\}$  and by Lemma 3 and Corollary 2 we have  $\text{HSP}\{\mathcal{G}_7\} = \Sigma$ . The proof that  $\text{HSP}\{\mathcal{G}_8\} = \Sigma$  is similar - it is enough to consider two congruences  $R_3 = e(\{\{a\}, \{b\}, \{c, d\}\})$  and  $R_4 = e(\{\{a, b\}, \{c\}, \{d\}\})$ .

To prove that  $\mathcal{G}_7$  and  $\mathcal{G}_8$  are the only 4-element groupoids generating  $\Sigma$  let us assume that  $\mathcal{G} = (\{a, b, c, d\}; \cdot) \in \Sigma$ . By (iii) we have  $1 \leq |I| \leq 4$ . If  $|I| = 4$ , then any  $G_i$  is one element and by (iii)  $x \cdot y = x$  for any  $x, y \in \{a, b, c, d\}$ . Thus  $\mathcal{G}$  belongs to  $\Sigma_0$  and does not generate  $\Sigma$  by Theorem 1. The same case holds if  $|I| = 1$ .

In general, if  $\mathcal{G}$  satisfies  $x \cdot y = x$ , then it cannot generate  $\Sigma$ . Excluding this case we have the following possibilities for  $\mathcal{G}$ , up to permutations of the elements  $a, b, c, d$ :

(c<sub>1</sub>)  $\mathcal{G}$  is isomorphic to  $\mathcal{G}_7$  or  $\mathcal{G}_8$ .

For  $I = \{1,2\}$ ,  $G_1 = \{a,b,c\}$ ,  $G_2 = \{d\}$  we have possibilities:

(c<sub>2</sub>)  $a \cdot d = b$ ,  $b \cdot d = a$ ,  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_3$ .

(c<sub>3</sub>)  $a \cdot d = c$ ,  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_2$ .

(c<sub>4</sub>)  $a \cdot d = b \cdot d = c$  and  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_2$ .

For  $I = \{1,2\}$ ,  $G_1 = \{a,b\}$ ,  $G_2 = \{c,d\}$  we have possibilities:

(c<sub>5</sub>)  $a \cdot c = a \cdot d = b$ ,  $b \cdot c = b \cdot d = a$ ,  $c \cdot a = c \cdot b = d$ ,  $d \cdot a = d \cdot b = c$ ,  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_3$ .

(c<sub>6</sub>)  $a \cdot c = a \cdot d = b$ ,  $c \cdot a = c \cdot b = d$  and  $x \cdot y = x$  otherwise.

Then  $\mathcal{G} \in \Sigma_2$ .

(c<sub>7</sub>)  $a \cdot c = a \cdot d = b$ ,  $b \cdot c = b \cdot d = a$ ,  $x \cdot y = x$  otherwise. Then

$\mathcal{G} \in \Sigma_3$ .

(c<sub>8</sub>)  $a \cdot c = a \cdot d = b$  and  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_2$ .

For  $I = \{1,2,3\}$ ,  $G_1 = \{a,b\}$ ,  $G_2 = \{c\}$ ,  $G_3 = \{d\}$  we have

possibilities:

(c<sub>9</sub>)  $a \cdot c = b$  and  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_2$ .

(c<sub>10</sub>)  $a \cdot c = b$ ,  $b \cdot c = a$ ,  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_3$ .

(c<sub>11</sub>)  $a \cdot c = a \cdot d = b$ ,  $x \cdot y = x$  otherwise. Then  $\mathcal{G} \in \Sigma_2$ .

(c<sub>12</sub>)  $a \cdot c = a \cdot d = b$ ,  $b \cdot c = b \cdot d = a$ ,  $x \cdot y = x$  otherwise.

Then  $\mathcal{G} \in \Sigma_3$ .

However, by Theorem 1 only in the case (c<sub>1</sub>),  $\mathcal{G}$  generates  $\Sigma$

Finally, if  $\mathcal{G}$  has less than 4 elements and belongs to  $\Sigma$ , then in its decomposition into subdirect product of subdirectly irreducible groupoids from  $\Sigma$ ,  $\mathcal{G}_4$  and  $\mathcal{G}_6$  cannot occur.

If only  $\mathcal{G}_2$  or  $\mathcal{G}_3$  occur, then  $\mathcal{G} \in \Sigma_3$  and does not generate  $\Sigma$ .

If only  $\mathcal{G}_2$  or  $\mathcal{G}_5$  occur, then  $\mathcal{G} \in \Sigma_2$  and does not generate  $\Sigma$ .

If  $\mathcal{G}_3$  and  $\mathcal{G}_5$  occur, then  $\mathcal{G}$  is isomorphic both to  $\mathcal{G}_3$

and to  $\mathcal{G}_5$  by projections, which is a contradiction since  $\mathcal{G}_3$  is not isomorphic to  $\mathcal{G}_5$ .
