CYCLIC ORDERED GROUPS AND MV-ALGEBRAS

DANIEL GLUSCHANKOF, Angers and Paris

(Received September 10, 1991)

In the forties and fifties two—at the moment—unrelated concepts derived from that of an ordered group appeared. The notion of cyclic-ordered group (c-group) (see [9], [10], [13] and [14]) and that of MV-algebra (see [4] and [5]). The first one appeared as a way of generalizing the notion of totally ordered groups. That notion was further extended to that of partially cyclically ordered groups. The notion of MV-algebras resulted from a succesfull attempt of giving an algebraic structure to the infinite-valued Lukasievicz propositional logics. In the last decade, that theory was fruitfully linked with that of a class of $\mathbf{C}^*$-algebras (see [8]). The objective of this work is to show that suitable subclasses of that notions can be linked by the way of a covariant functor.

1. DEFINITIONS AND FIRST FACTS

A cyclically ordered group (c-group) is a system $\langle G,+,-,0,T\rangle$ where $\langle G,+,-,0\rangle$ is a group (not necessarilly commutative) and T is a ternary relation verifying the following properties:

C1. $\forall abc$ (if $a \neq b \neq c \neq a$ then exactly one of $T(a,b,c)$ and $T(a,c,b)$ holds);

C2. $\forall abc\ \big(T(a,b,c) \Longrightarrow a \neq b \neq c \neq a\big)$;

C3. $\forall abc\ \big(T(a,b,c) \Longrightarrow T(c,a,b)\big)$;

C4. $\forall abcd\ \big(T(b,c,a)\ \&\ T(c,d,a) \Longrightarrow T(b,d,a)\big)$;

C5. $\forall abcd\ \big(T(a,b,c) \Longrightarrow T(d+a,d+b,d+c)\ \&\ T(a+d,b+d,c+d)\big)$.

A fundamental result of Rieger (see [9]) says that any such a group is isomorphic to a quotient of a totally ordered group (o-group) by the subgroup generated by a strong unit (a cofinal element in its centre). In that case, if $G = \langle G,+,-,0,u,\leqslant\rangle$ is an o-group with strong unit u, the quotient group $G_u = G/\langle u\rangle$ can be endowed with a cyclic order by defining $T(a,b,c)$ if and only if, for the only representatives a, b, c such that $0 \leqslant a,b,c < u$, either $a<b<c$ or $b<c<a$ or $c<a<b$ holds.

The notion of c-group generalizes that of totally ordered groups (o-groups) in the sense that for a c-group with the property: for all $a \in G$, $T(-a, 0, a)$ implies, for all $n \in \mathbb{N}$, $T(-na, 0, na)$ a total order (compatible with the group operation) can be defined by $0 < a$ if and only if $T(-a, 0, a)$. Conversely, an o-group can be endowed with a c-group structure by defining $T(a, b, c)$ if and only if $a < b < c$ or $b < c < a$ or $c < a < b$.

A partially cyclically ordered group (pco-group) is a system $\langle G, +, -, 0, T \rangle$ where the axioms C3, C4, C5 and

C1p. $\forall abc(T(a,b,c) \Longrightarrow \neg T(a,c,b))$;

C6. $\forall abc(T(a,b,c) \Longrightarrow T(-c,-b,-a))$ hold.

This last axiom is consequence of axioms C1 ... C5 and C2 is consequence of C1p and C3.

Observe that, Rieger's theorem also holds in this case by replacing the o-group by a partially ordered group (po-grup) (see [13] or [14]).

An MV-algebra (see [4], [5] and [8]) is a system $\langle A, \oplus, *, \neg, 0, 1 \rangle$ which satisfies the following universal identities:

m_1	$x \oplus (y \oplus z) = (x \oplus y) \oplus z$
m_2	$x \oplus 0 = x$
m_3	$x \oplus y = y \oplus x$
m_4	$x \oplus 1 = 1$
m_5	$\neg\neg x = x$
m_6	$\neg 0 = 1$
m_7	$x \oplus \neg x = 1$
m_8	$\neg(\neg x \oplus y) \oplus y = \neg(x \oplus \neg y) \oplus x$
m_9	$x * y = \neg(\neg x \oplus \neg y)$

By defining $x \vee y := (x * \neg y) \oplus y$ and, by duality, $x \wedge y := \neg(\neg x \vee \neg y)$ we have that $\langle A, \vee, \wedge, 0, 1 \rangle$ is a bounded distributive lattice.

Another approach for this structures is that of Wajsberg algebras (W-algebras) (see [6] and [11]). Such an algebra is a system $\langle A, \rightarrow, \neg, 0, 1 \rangle$ satisfying the following universal identities:

W1. $(x \to y) \to ((y \to z) \to (x \to z)) = 1;$

W2. $(x \to y) \to y = (y \to x) \to x;$

W3. $(\neg x \to \neg y) \to (y \to x) = 1;$

W4. $1 \to x = x;$

W5. $x \to 0 = \neg x;$

W6. $\neg 1 = 0;$

W7. $\neg 0 = 1.$

By defining $x \vee y := (x \to y) \to y$ and $x \wedge y := \neg(\neg x \vee \neg y)$ $\langle A, \vee, \wedge, 0, 1\rangle$ results also a bounded distributive lattice.

In [6] it is proved that a W-algebra can be thought of as an MV-algebra (and viceversa) by identifying the respective 0,1 and $\neg$ and defining:

$$a \to b := \neg a \oplus b \qquad \text{and} \qquad a \oplus b := \neg a \to b;$$

(recall that the operation $*$ of the MV-algebra can be defined in terms of $\oplus$ and $\neg$).

In [4] it is proved that any MV-algebra A can be obtained from an abelian lattice-ordered group (l-group) with strong unit u $G = \langle G, \vee, \wedge, +, -, 0, u\rangle$ by defining:

$$A = [0, u] = \{a \mid 0 \leqslant a \leqslant u\}; \quad a \oplus b = (a + b) \wedge u; \quad \neg a = u - a \text{ and } 1 = u.$$

Since any MV-algebra derives from an abelian l-group, in the sequel group will stand for abelian group, homomorphism and subgroup for homomorphism and subgroup for the respective structures (o-groups, c-groups, pco-groups, l-groups, MV-algebras).

2. Lattice pco-groups

For any pco-group G, a partial order be defined by

$$(*) \qquad a \leqslant b \quad \text{if and only if} \quad a = b \quad \text{or} \quad T(0, a, b) \quad \text{or} \quad a = 0.$$

This order makes every element "positive". Observe that, in general, $\leqslant$ is not compatible with the group operation, for example, by setting $G = \mathbb{Z}/3\mathbb{Z}$ with its natural cyclical order, the total order $(*)$ induced is given by the set of pairs $\{(0,0), (1,1), (2,2), (0,1), (0,2), (1,2)\}$ which is obviously non-compatible, since $1 \leqslant 2$ holds but $2 = 1 + 1 \leqslant 2 + 1 = 0$ does not hold.

We say that a group homomorphism $f: G \to H$ between pco-groups is a pco-homomorphism if, for $a, b, c \in G$ such that $T(a, b, c)$, if $f(a) \neq f(b) \neq f(c) \neq f(a)$ then $T(f(a), f(b), f(c))$.

Observe that a pco-homomorphism is also a homomorphism for the order given in $(*)$.

Definition 2.1. A pco-group G will be called a lattice-cyclical-group (and denoted lc-group), if, for the order defined in (*) the structure $\langle G, 0, \leqslant \rangle$ admits a distributive lattice structure with first element.

Lemma 2.2. *Let G be an lc-group, $a, b \in G$. If $a \leqslant a+b$ $(b \leqslant a+b)$ then $b \leqslant a+b$ $(a \leqslant a+b)$, implying $a \vee b \leqslant a+b$.*

Proof. Suppose $0 < a < a+b$ (the other cases are immediate). Then we have $T(0, a, a+b)$, which, adding $-(a+b)$ to each term, implies $T(-(a+b), -b, 0)$ which, by axiom C6, is equivalent to $T(0, b, a+b)$, proving our claim. □

Definition 2.3. Let G be an lc-group and H a subgroup.

(i) H is called an lc-ideal if it is convex for the order $\leqslant$ (that is, for all $x \in H$, $z \in G$, $z \leqslant x$ implies $z \in H$), and is an l-subgroup (that is, for $x, y \in H$, $x \vee y \in H$).

(ii) H is called a pc-subgroup if it is convex for the relation T (that is, for $x, y \in H$ and $z \in G$, $T(x, z, y)$ implies $z \in G$).

Observe that the lc-ideals (pc-subgroups) are the kernels of lc(pc)-homomorphisms. Moreover, the lc-ideals are lattice-ideals for the structure $\langle G, 0, \vee, \wedge \rangle$. Observe also that for cyclically ordered groups, the T-convex subgroups are always trivial.

Lemma 2.4. *Let G be an lc-group and H a subgroup. H is T-convex if and only if it is $\leqslant$-convex. So, any pc-subgroup preserving the lattice operations is also an lc-ideal.*

Proof. Let H be T-convex, $a \in H$, $b \in G$ such that $0 \leqslant b \leqslant a$. If $b = 0$ or $b = a$, it is immediate that $b \in H$. So we can write $T(0, b, a)$, implying, by T-convexity, that $b \in H$.

For the converse, if H is $\leqslant$-convex, $a, c \in H$, $b \in G$ such that $T(a, b, c)$. By axiom C5 we have $T(0, b-a, c-a)$. Since H is $\leqslant$-convex, we conclude that $b - a \in H$ and then $b \in H$. □

So, without abuse of notation, we can speak about convex subgroups.

Lemma 2.5. *Let G be an lc-group, $H \subseteq G$ an lc-ideal. H is prime if and only if the quotient G/H is cyclically ordered.*

Proof. By a result on distributive lattices (see [1, III.3]) we have that the lattice $\langle G/H, 0, \vee, \wedge\rangle \simeq \langle G, 0, \vee, \wedge\rangle / H$ is totally ordered if and only if H is prime as a lattice ideal. Since the notion of primeness is a set theoretic one, H is prime as lattice ideal if and only if it is so as lc-ideal. It is immediate to verify that the induced order $\leqslant$ on a pco-group is total if and only if the group is cyclically ordered. □

As in the case of l-groups, we can define the notions of orthogonality, projectability and weak unit:

Definitions 2.6. Let G be an lc-group, $g, h \in G$, A, B subsets of G.

(i) g and h are orthogonal, $g \perp h$, if $g \wedge h = 0$.

(ii) The polar of A, $A^{\perp} = \{x \mid \forall a(a \in A \Rightarrow x \perp a)\}$. B is called a polar if $B = A^{\perp}$ for some A. If $A = \{g\}$ we shall write $g^{\perp}$ in place of $\{g\}^{\perp}$.

(iii) The double polar of A, $A^{\perp\perp} = \{x \mid \forall y(y \in A^{\perp} \Rightarrow x \perp y)\}$. Observe that B is a double polar if and only if it is a polar.

(iv) G is called projectable if one can define a binary operation pr on G, compatible for the left argument with the group operations, such that, $h' = \mathrm{pr}(g, h)$ implies $h' \in h^{\perp}$ and $g - h' \in h^{\perp\perp}$.

(v) $u \in G$ is called a weak unit if, for all $g \in G$, $g \perp u$ implies $g = 0$.

Lemma 2.7. *Let G be a projectable lc-group. Its polars are lc-ideals.*

Proof. Let $g, h \in G$, A a subset of G. Consider a generic $a \in A$. By distributivity, it is immediate that $(g \vee h) \wedge a = (g \wedge a) \vee (h \wedge a)$. Since $g \leqslant h$ implies $g \wedge a \leqslant h \wedge a$, we have that $h \in a^{\perp}$ implies $g \in a^{\perp}$. Since $A^{\perp} = \bigcup\{a^{\perp} \mid a \in A\}$, we conclude that $A^{\perp}$ is a lattice-ideal. Suppose $g \perp a$ and $h \perp a$. By projectability, observe that $g = \mathrm{pr}(g, a)$ and $h = \mathrm{pr}(h, a)$. Since pr is compatible at left with the sum and the inverse, we have that $\mathrm{pr}(g + h, a) = g + h$ and $\mathrm{pr}(-g, a) = -g$, implying $(g + h) \perp a$ and $-g \perp a$. So we can conclude that $A^{\perp}$ is an lc-ideal. □

Lemma 2.8. *Let G be a projectable lc-group, $h, h_1, h_2, h_3, h_4 \in G$ such that $h_1, h_3 \in h^{\perp}$; $h_2, h_4 \in h^{\perp\perp}$ and $h_1 + h_2 = h_3 + h_4$ then $h_1 = h_3$ and $h_2 = h_4$.*

Proof. We have $h_1 + h_2 = h_3 + h_4$ implies $h_1 - h_3 = h_4 - h_2$. Since the polars are lc-ideals, we have that the first member belongs to $h^{\perp}$ and the second to $h^{\perp\perp}$, implying that both equal zero. □

From the above proved lemma, we conclude that the decomposition in terms of $h^{\perp}$ and $h^{\perp\perp}$ given by $\mathrm{pr}(\ , h)$ is the only one possible and, since $\mathrm{pr}\big(\mathrm{pr}(g, h), h\big) = \mathrm{pr}(g, h)$ it can be well considered a projection.

We recall (see [3; § 8.1]) that given a language L, an L-structure G and a family $(L_i)_{i\in I}$ of L-structures, G is a Boolean product of the family $(L_i)_{i\in I}$ (denoted by $G \in \Gamma\big(I, (L_i)_{i\in I}\big)$) if and only if:

(i) G is a subdirect product of the family $(L_i)_{i\in I}$ and

(ii) I can be endowed with a Boolean space topology such that:

(α) For any atomic L-formula $\varphi(x_1,\ldots,x_n)$ and $g_1,\ldots,g_n \in G$, the set $\{i \mid L_i \models \varphi[g_1(i),\ldots,g_n(i)]\}$ (denoted by $[\![\varphi[g_1,\ldots,g_n]]\!]$) is clopen;

(β) For $g,h \in G$ and J a clopen set of I, there exists the element of G given by $g \restriction J \cup h \restriction I\setminus J$ (patchwork property).

Let $(C_i)_{i\in I}$ be a family of c-groups and G a subgroup of $\prod C_i$. G will be endowed with a pco structure by considering the product ternary relation $T = \prod T_i$. That is $T(a,b,c)$ if and only for all $i \in I$ $T(a_i,b_i,c_i)$ holds.

The following proposition is analogous to a result of Weispfenning on l-groups (see [12]):

Proposition 2.9. *An lc-group G is isomorphic to a Boolean product (in the language $\langle +,-,0,T,\vee,\wedge\rangle$) of (non-trivial) c-groups if and only if it is projectable and has a weak unit.*

Proof. Let $G \in \Gamma(I,(C_i)_{i\in I})$ where $(C_i)_{i\in I}$ is a family of non-trivial c-groups. For each $i \in I$ there exists $h_i \in C_i$ such that $h_i \neq 0$. Since G is a subdirect product, there exist a family $(h_i')_{i\in I} \subseteq G$ such that, for each $i \in I$, $h_i'(i) = h_i$. By property (ii-α) above, for each $i \in I$, the set $[\![h_i' \neq 0]\!]$ is clopen. By compacity of I, a finite subset J of I can be found such that the family $\{[\![h_i' \neq 0]\!] \mid i \in J\}$ covers I. By property (ii-β), that family can be considered disjoint. Now, applying $|J|$ times the same property, an element $h \in G$ such that $h \restriction [\![h_i' \neq 0]\!] = h_{i|[h_i' \neq 0]}$ $(i \in J)$ can be found. (This line of argumentation on Boolean products is standard and will not be repeated in the following proofs.) We shall see that h is, indeed, a weak unit. For, suppose $g \in G$ and $g \wedge h = 0$. Since G is a subdirect product and $x \wedge y = 0$ is an atomic formula, for each $i \in I$, $g(i) \wedge h(i) = 0$ holds. But, for each c-group C_i, $h(i)$ is different from 0, implying that $g(i) = 0$ for all i and then $g = 0$.

For the projectability, let $g,h \in G$. Consider the clopen subset of I $J = [\![h \neq 0]\!]$. By property (ii-β) call h'' the restriction of g to J and h' its restriction to $I \setminus J$. It is immediate to verify (since G is a subdirect product) that $g = h' + h''$ and $h' = \mathrm{pr}(g,h)$.

For the converse. Let G be a projectable lc-group with weak unit u. We consider the Boolean algebra $B(G,u)$ with underlying set $\{\mathrm{pr}(u,g) \mid g \in G\}$ and operations $\mathrm{pr}(u,g) \vee \mathrm{pr}(u,h) = \mathrm{pr}(u, g \wedge h)$; $\neg\,\mathrm{pr}(u,g) = u - \mathrm{pr}(u,g) = \mathrm{pr}\,(u, \mathrm{pr}(u,g))$; $0_B = \mathrm{pr}(u,u) = 0$ and $1 = \mathrm{pr}(u,0) = u$. It is easy to verify that, if u, u' are weak units, we have the isomorphism $B(G,u) \simeq B(G,u')$. So we can forget the weak unit and write $B(G)$ for the Boolean algebra of the group. Observe that polars of G and ideals of $B(G)$ are in a bijective correspondence: If A is a polar of G, $A \cap B(G)$ is an ideal of $B(G)$. If J is an ideal of $B(G)$, $J^G = \{g \in G \mid u - \mathrm{pr}(u,g) \in J\}$ is a polar of G. Both constructions are each other inverses.

Let $I = \mathrm{Sp}(B(G))$ the space of prime ideals of $B(G)$. By the above remark and Lemma 2.7, we can identify it as a subspace of the space of prime lc-ideals of G. That set of lc-ideals distinguishes points: In particular, if $g \in G$, $g \neq 0$, there exists a prime ideal P of $B(G)$ such that $u - \mathrm{pr}(u, g) \notin P$. Then $g/p^G \neq 0$. So G can be represented as a subdirect product of the family $(C_i)_{i \in I}$ of lc-groups given by the quotients by the elements of I. Since, each of those lc-ideals is prime, by Lemma 2.5, each C_i results cyclically ordered for the quotient of the relation T.

Finally we show that G (considered as a subdirect product) has properties (ii-α) and (ii-β) of the Boolean product definition. Any atomic formula $\varphi(\overline{x})$ is of the form or $T(t_1(\overline{x}), t_2(\overline{x}), t_3(\overline{x}))$ or $t_1(\overline{x}) = t_2(\overline{x})$ for t_1, t_2, t_3 terms in the group language.

For the sake of simplicity, we can suppose that the terms are just variables. We have, for a c-group $T(x_1, x_2, x_3) \Leftrightarrow T(0, x_2 - x_1, x_3 - x_1) \Leftrightarrow 0 < x_2 - x_1 < x_3 - x_1 \Leftrightarrow (x_2 - x_1) \vee (x_3 - x_1) = x_3 - x_1 \ \&\ x_2 - x_1 \neq 0 \ \&\ x_3 - x_2 \neq 0$. Let be now $g_1, g_2, g_3 \in G$, call $b = \neg \mathrm{pr}(u, g_2 - g_1)$, $a = \mathrm{pr}\,(u, g_3 - g_1 - ((g_2 - g_1) \vee (g_3 - g_1)))$ and $c = \neg \mathrm{pr}(u, g_3 - g_2)$. Now, by the above considerations about the definition of T on a subgroup of a product of c-groups, the element $a \wedge b \wedge c$ of the Boolean algebra $B(G)$ corresponds to $[\![T(g_1, g_2, g_3)]\!]$. And since the elements of $B(G)$ are in correspondence with the clopen sets of $\mathrm{Sp}(B(G))$, we are done. For the formula $x_1 = x_2$, and $g_1, g_2 \in G$, it suffices to take $a = \mathrm{pr}(u, g_1 - g_2)$, proving property (ii-$\alpha$).

Property (ii-β) results from projectability. Let $g, h \in G$ and J a clopen set of I, there exists then $c_J \in G$ such that $c_J = \mathrm{pr}(u, u - c_J) = \neg \mathrm{pr}(u, c_J)$ and that element "corresponds" to J. So, we have the identity $g \restriction J \cup h \restriction I \setminus J = \mathrm{pr}(g, u - c_J) + \mathrm{pr}(h, c_J)$. □

3. The standard construction

We recall the result of V. Weispfenning (see [12]), which states that an l-group is isomorphic to a Boolean product of totally ordered groups if and only if it is projectable and has a weak unit.

Let G be a projectable l-group and $u \in G$ a strong unit. Define the l-subgroup $H(u)$ generated by all the elements of the form $u \restriction g^{\perp}$ (with g ranging by all the elements of G). Consider the quotient group $G_u = G/H(u)$.

Proposition 3.1. *The group G_u admits a natural lc-structure.*

P r o o f. By the above stated observation, we shall consider $G \in \Gamma(I, (L_i)_{i \in I})$ for some family $(L_i)_{i \in I}$ of totally ordered groups. First, observe that, for any $g_u \in G_u$ there exists only one $a \in [0, u) = \{h \in G \mid 0 \leqslant h < u\}$ such that $a_u = g_u$: Let be $g \in G$. Since u is a strong unit, we have that there exists $n \in \mathbb{N}$ such that $nu > |g|$. For $m \in \mathbb{Z}$ such that $-n \leqslant m < n$, call I_m the clopen subset of I given by

$[\![mu \leqslant g < (m+1)u]\!]$. Calling g_m the restriction of g to I_m, we have that it has a representative in the interval $[0, u_m)$. Now, by the patchwork property, we can patch all those representatives and obtain an element $a \in [0, u)$ such that $a_u = g_u$. It is immediate that any two of the elements in the interval are not congruent modulo $H(u)$.

Now, for $a_u, b_u, c_u \in G_u$, consider the representatives $a, b, c \in [0, u)$. We shall define $T(a_u, b_u, c_u)$ if and only if

$$I = [\![a < b < c \text{ or } b < c < a \text{ or } c < a < b]\!].$$

The proof that this defines a partial cyclic order is analogous to that for the cyclic order case (see [10]).

Call $\leqslant_u$ the order induced by T. It is immediate to verify that $a_u \leqslant_u b_u$ if and only if $a \leqslant b$ for a, b representatives in $[0, u)$. Since for this order that interval is a distributive lattice with first element, we can conclude that its lattice structure is copied, isomorphically on G_u. □

The Boolean product characterization allows us to prove the converse.

Proposition 3.2. *Let G be a projectable lc-group with weak unit. There exists an l-group G' with a strong unit u such that $G \simeq G'$ in the above sense.*

Proof. We can suppose $G \in \Gamma(I, (C_i)_{i \in I})$ for some family $(C_i)_{i \in I}$ of c-groups. By Rieger's theorem, there exists a family $(L_i, u_i)_{i \in I}$ of o-groups with strong units such that for each $i \in I$, $C_i \simeq (L_i)/\langle u_i \rangle$. Consider now the direct product $\prod L_i$ and identify the elements of G with the elements in the product of intervals $\prod [0, u_i)$. Now call G' the l-group spanned by G and $(u_i)_{i \in I}$ in $\prod L_i$. By construction, it results that $G' \in \Gamma(I, (L_i)_{i \in I})$ and it is immediate to prove that, setting $u = (u_i)_{i \in I}$, $G \simeq G'_u$. □

4. The functorial equivalence

In the sequel we shall restrict ourselves to projectable MV-algebras, which can be defined analogously to the case of lc(l)-groups. In particular, it holds that a projectable MV-algebra is isomorphic to an element of $\Gamma(I, (L_i))_{i \in I}$ for a family $(L_i)_{i \in I}$ of totally ordered MV-algebras. (This result is analogous of that of Weispfenning on l-groups and can be found—implicitly—in [11]).

In an MV-algebra, an element a is called boolean if $a \perp \neg a$.

Let $A = \langle A, \oplus, *, \neg, 0, 1 \rangle$ be an MV-algebra and consider the equivalence relation $\sim$ given by:

$a \sim b$ if and only if there exist boolean elements a' and b' such that $a \oplus a' = b \oplus b'$, $a \perp a'$, $b \perp b'$ and $a' \perp b'$. By considering A as a boolean product over a space I, this corresponds to the identity $I = [\![a = b]\!] \cup [\![a = 0 \ \& \ b = 1]\!] \cup [\![b = 0 \ \& \ a = 1]\!]$. We show that $\sim$ is, indeed, an equivalence relation:

- By taking $a' = 0$, we prove that $a \sim a$.
- The simmetry results from the definition.
- Let be $a \sim b \sim c$. We shall use the boolean product characterization of the relation $\sim$:

$$I_1 = [\![a = c]\!] = ([\![a = b]\!] \cap [\![b = c]\!]) \cup [\![a = 0 \ \& \ c = 0]\!] \cup [\![a = 1 \ \& \ c = 1]\!];$$
$$I_2 = [\![a = 0 \ \& \ c = 1]\!] = ([\![a = b]\!] \cap [\![b = 0 \ \& \ c = 1]\!]) \cup ([\![c = b]\!] \cap [\![b = 1 \ \& \ a = 0]\!]);$$
$$I_3 = [\![a = 1 \ \& \ c = 0]\!] = ([\![a = b]\!] \cap [\![b = 1 \ \& \ c = 0]\!]) \cup ([\![c = b]\!] \cap x[\![b = 0 \ \& \ a = 1]\!]).$$

A simple set-theoretic manipulation proves that $I = I_1 \cup I_2 \cup I_3$ and then $a \sim c$.

We define the group operations in $G = A/\sim$ by

$$-(a/\sim) := \neg a/\sim.$$

Given $a/\sim, b/\sim \in G$ consider the clopen set $J = [\![a \oplus b < 1]\!]$ and define

$$(a/\sim) + (b/\sim) := \big((a \oplus b)\big|J \cup (a * b)\big|I \setminus J\big)/\sim.$$

To verify that those operations are well-defined, since we are dealing with subdirect products, it suffices to consider the totally ordered case:

For that case we have $a \sim b$ if and only if $a = b$ or ($a = 0$ and $b = 1$) or ($a = 1$ and $b = 0$). For the difference: $\neg 0/\sim = 1/\sim = 0/\sim = \neg 1/\sim$. For the sum, it suffices to consider the case $a/\sim = 0/\sim$ and $0 < b < 1$. So we have $0/\sim + b/\sim = (0 \oplus b)/\sim = b/\sim = (1 * b)/\sim = 1/\sim + b/\sim$. We show that $\langle G, +, -, 0\rangle$ is an abelian group:

Recall the Theorem 16 in [6] which implies that the variety of MV-algebras is generated by the MV-algebra $\mathbf{Q}[0,1]$ with underlying set $\{x \in \mathbf{Q} \mid 0 \leqslant x \leqslant 1\}$ and operations $x \oplus y = 1 \wedge (x + y)$ and $\neg x = 1 - x$. So any equation is true in the variety if and only if it holds in $\mathbf{Q}[0,1]$. We shall consider then $A = \mathbf{Q}[0,1]$.

- The commutativity results from that of $\oplus$ and $*$;
- $a/\sim + 0/\sim = (a \oplus 0)/\sim = a/\sim$;
- $-a/\sim + \big(-(a/\sim)\big) = a/\sim + \neg a/\sim = (a * \neg a)/\sim = 0/\sim$ because $a \oplus \neg a = 1$;
- For the associativity, let $a/\sim, b/\sim, c/\sim \in G$:

Case $(a \oplus b) \oplus c < 1$: Results from the associativity of $\oplus$;

Case $a \oplus b = 1$ and $(a * b) \oplus c = 1$: Since $a * b \leqslant b$, we have $b \oplus c = 1$ and then

$$(a/\sim + b/\sim) + c/\sim = (a * b) * c. \tag{1}$$

$a\oplus(b*c) = 1\wedge(a+(b*c)) = 1\wedge(a+\neg(\neg b\oplus\neg c)) = 1\wedge(a+(1-(1\wedge(1-b+(1-c))))) = 1\wedge(a+(1-(1\wedge(2-(b+c))))) = 1\wedge(a+(1-(2-(b+c)))) = 1\wedge(a+b+c-1) = (a*b)\oplus c$ because $a*b = a+b-1$. And, by hipothesis, $(a*b)\oplus c = 1$. So we have $a/\!\sim + (b/\!\sim + c/\!\sim) = (a*b)*c$ which coincides with (1).

Case $a\oplus b = 1$, $(a*b)\oplus c < 1$ and $b\oplus c < 1$:

$$\begin{aligned}
&(a/\!\sim + b/\!\sim) + c/\!\sim = (a*b)\oplus c = 1\wedge(a*b+c) = 1\wedge(\neg(\neg a\oplus\neg b)+c) = \\
(2)\quad &= 1\wedge(1-(1\wedge(1-a+(1-b)))+c) = 1\wedge(1-(1\wedge(2-(a+b)))+c) = \\
&= 1\wedge(1-(2-(a+b))+c) = 1\wedge(a+b+c-1).
\end{aligned}$$

Since $a\oplus(b\oplus c) \geqslant a\oplus b = 1$, we have $a/\!\sim + (b/\!\sim + c/\!\sim) = a*(b\oplus c)$. An analogous treatment yields $a*(b\oplus c) = (2)$.

The rest of the cases are treated in a similar way, proving the associativy.

Now, for the relation T, given $a/\!\sim, b/\!\sim, c/\!\sim \in G$, define the following clopen sets:

$$\begin{aligned}
I_1 &= [\![(a<b<c)\ \&\ (a\neq 0 \text{ or } c\neq 1)]\!],\\
I_2 &= [\![(b<c<a)\ \&\ (b\neq 0 \text{ or } a\neq 1)]\!],\\
I_3 &= [\![(c<a<b)\ \&\ (c\neq 0 \text{ or } b\neq 1)]\!].
\end{aligned}$$

Define a pc-order by $T(a/\!\sim, b/\!\sim, c/\!\sim)$ if and only if $I = \bigcup_{j=1}^{3} I_j$. It is immediate that T satisfies properties C1p, C3, C4, C5 and C6. The good definition results from the second condition in each I_j. Since the order $\leqslant_c$ defined on G by $g \leqslant_c h$ if and only if $T(0,g,h)$ or $g = 0$ or $g = h$ coincides with the order $\leqslant$ of A (modulo $\sim$), we have that it induces a lattice structure.

For the compatibility of $+$ and T it also suffices to consider the totally ordered case: Let be $a,b,c,d \in A$ such that $a<b<c<1$ and $d<1$.

- If $c\oplus d < 1$ we have $a\oplus d < b\oplus d < c\oplus d < 1$;
- If $a\oplus d = b\oplus d = c\oplus d = 1$, we have $a*d < b*d < c*d$;
- If $a\oplus d, b\oplus d < 1$ and $c\oplus d = 1$ we have $c*d < d \leqslant a\oplus d < b\oplus d$;
- The case $a\oplus d < 1$ and $b\oplus d, c\oplus d = 1$ is analogous.

If $f\colon A \longrightarrow B$ is an MV-homomorphism, it is immediate to verify that $f/\!\sim$ is well-defined and then, an lc-group homomorphism.

Reciprocally, let $G = \langle G,+,-,0,u,T\rangle$ be a projectable lc-group with weak unit. We can identify G with an element of $\Gamma(I,(L_i)_{i\in I})$ for some family $(L_i)_i \in I$ of c-groups, where the Boolean space I is the one constructed in the second part of the proof of Proposition 2.9. The Boolean algebra $B(I)$ of clopen sets of I (considered as a set algebra) can be also identified with the algebra of supports of elements of G.

Define $A = \{(g,\alpha) \in G\times B(I) \mid \mathrm{supp}(g)\cap\alpha = \emptyset\}$.

We define on A the MV operations:

The 0 of the MV-algebra will be the element $(0, \emptyset)$ and the 1 the element $(0, I)$.

Let $(g, \alpha) \in A$, call $\beta = I \setminus \operatorname{supp}(g)$. Define $\neg(g, \alpha) = \big(-g, (I \setminus \alpha) \cap \beta\big)$.

Given $(g, \alpha), (h, \beta) \in A$, consider the clopen set $\gamma = I \setminus (\alpha \cup \beta)$ and the elements of G $g' = g|\gamma$ and $h' = h|\gamma$. Call δ the clopen set $\gamma \cap \big([\![T(0, g', g' + h')]\!] \cup [\![g' = 0]\!] \cup [\![h' = 0]\!]\big)$ which coincides with $\gamma \cap [\![g' \leqslant g' + h']\!]$. (Observe that Lemma 2.2 implies $T(0, g', g' + h')$ if and only if $T(0, h', g' + h')$). And finally $\eta = [\![\neg T(0, g', g' + h')]\!]$. Now define:

$$(g, \alpha) \oplus (h, \beta) = \big((g' + h')|\delta, \alpha \cup \beta \cup \eta\big).$$

The operation $*$ is defined in terms of $\oplus$ and $\neg$.

We shall proof that $A = \langle A, \oplus, *, \neg, 0, 1\rangle$ is in effect an MV-algebra.

m_1: Let $(g, \alpha), (h, \beta), (k, \gamma) \in A$.

By setting

$$\delta = I \setminus \alpha \cup \beta \cup \gamma, \quad g' = g|\delta, \quad h' = h|\delta, \quad k' = k|\delta,$$
$$\varepsilon = [\![g' \leqslant g' + h' \leqslant g' + h' + k']\!], \quad \eta = \varepsilon \cap \delta$$

and

$$\kappa = \neg[\![g' \leqslant g' + h' \leqslant g' + h' + k']\!],$$

we have that $\big((g, \alpha) \oplus (h, \beta)\big) \oplus (k, \gamma) = (g, \alpha) \oplus (h, \beta) \oplus (k, \gamma) = \big((g' + h' + k')|\eta, \alpha \cup \beta \cup \gamma \cup \kappa\big)$, implying the associativity.

m_5: Let $(g, \alpha) \in A$, $\beta = I \setminus \operatorname{supp}(g)$, then $\neg(g, \alpha) = \big(-g, (I \setminus \alpha) \cap \beta\big)$. Since $\operatorname{supp}(-g) = \operatorname{supp}(g)$, we have $\neg\neg(g, \alpha) = \big(g, I \setminus \big((I \setminus \alpha) \cap \beta\big) \cap \beta\big) = (g, \alpha)$ because $\alpha \subseteq \beta$.

m_8: We shall prove that $\neg(\neg x \oplus y) \oplus y = x \vee y$, proving then the equation $\neg(\neg x \oplus y) \oplus y = \neg(x \oplus \neg y) \oplus x$. Let $(g, \alpha), (h, \beta) \in A$. Using the Boolean product characterization, we have $\neg(\neg x \oplus y) \oplus y = x \vee y$ if and only if, for each $i \in I$,

$$\big(\neg(\neg x \oplus y) \oplus y\big)(i) = \begin{cases} x(i) & \text{if } y(i) \leqslant x(i); \\ y(i) & \text{if } x(i) \leqslant y(i). \end{cases},$$

which translated to the elements of A results:

$\big(\neg(\neg(g, \alpha) \oplus (h, \beta)) \oplus (h, \beta)\big)(i) =$

$(g, \alpha)(i)$ if $T\big(0, h(i), g(i)\big)$ or $\big(g(i) \neq 0$ and $h(i) = g(i)\big)$ or $\big(g(i) = 0$ and $\alpha(i) = 1\big)$ or $h(i) = \beta(i) = 0$;

$(h, \beta)(i)$ if $T\big(0, g(i), h(i)\big)$ or $\big(h(i) \neq 0$ and $g(i) = h(i)\big)$ or $\big(h(i) = 0$ and $\beta(i) = 1\big)$ or $g(i) = \alpha(i) = 0$.

Case $g(i) = \alpha(i) = 0$:

$\neg(g, \alpha)(i) = (0, 1)$ and then $\big(\neg(\neg(g, \alpha) \oplus (h, \beta)) \oplus (h, \beta)\big)(i) = \big(\neg((0, 1) \oplus (h, \beta)) \oplus (h, \beta)\big)(i) = \big((0, 0) \oplus (h, \beta)\big)(i) = (h, \beta)(i)$.

Case $g(i)=0,\ \alpha(i)=1$:
$\neg(g,\alpha)(i)=(0,0)$ and then $\big(\neg(\neg(g,\alpha)\oplus(h,\beta))\oplus(h,\beta)\big)(i)=\big(\neg((0,0)\oplus(h,\beta))\oplus(h,\beta)\big)(i)=\big(\neg(h,\beta)\oplus(h,\beta)\big)(i)=(0,1)=(g,\alpha)(i)$.

Case $h(i)=\beta(i)=0$:
$\big(\neg(\neg(g,\alpha)\oplus(h,\beta))\oplus(h,\beta)\big)(i)=\big(\neg(\neg(g,\alpha)\oplus(0,0))\oplus(0,0)\big)(i)=\neg\neg(g,\alpha)(i)=(g,\alpha)(i)$.

Case $h(i)=0,\ \beta(i)=1$:
$\big(\neg(\neg(g,\alpha)\oplus(h,\beta))\oplus(h,\beta)\big)(i)=\big(\neg(\neg(g,\alpha)\oplus(0,1))\oplus(0,1)\big)(i)=(0,1)=(h,\beta)(i)$.

Case $T\big(0,g(i),h(i)\big)$, that is $0<g(i)<h(i)$ and $\alpha(i)=\beta(i)=0$:
that implies $\neg(g,\alpha)(i)=(-g,0)(i)>(-h,0)(i)=\neg(h,\beta)(i)$, and then

$$\neg(g,\alpha)(i)\oplus(h,\beta)(i)=(0,1),$$

concluding that

$$\big(\neg(\neg(g,\alpha)\oplus(h,\beta))\oplus(h,\beta)\big)(i)=\neg(0,1)\oplus(h,\beta)(i)=(h,\beta)(i).$$

Case $T\big(0,h(i),g(i)\big)$, that is $0<h(i)<g(i)$ and $\alpha(i)=\beta(i)=0$:
Since $\neg(g,\alpha)(i)<\neg(h,\beta)(i)$, we have $\neg(g,\alpha)(i)\oplus(h,\beta)(i)<(0,1)$, implying $\neg(g,\alpha)(i)\oplus(h,\beta)(i)=(-g+h,0)(i)$. Then $\big(\neg(\neg(g,\alpha)\oplus(h,\beta))\oplus(h,\beta)\big)(i)=\big(\neg(-g+h,0)\big)\oplus(h,0)(i)=\big((g-h,0)(i)\big)\oplus(h,0)(i)$ which is equal to $(g,0)(i)$ because we have $T\big(0,g(i)-h(i),g(i)\big)$.

Case $g(i)=h(i)\neq 0=\alpha(i)=\beta(i)$:
We have $\neg(g,\alpha)(i)=\neg(h,\beta)(i)$.
So $\big(\neg(\neg(g,\alpha)\oplus(h,\beta))\oplus(h,\beta)\big)(i)=\big(\neg(0,1)\oplus(h,\beta)\big)(i)=\big((0,0)\oplus(h,\beta)\big)(i)$ which equals to $(h,\beta)(i)$.

m_2, m_3, m_4, m_6 and m_7 are immediate and m_9 can be considered a definition.

If $f\colon G\to H$ is an lc-homomorphism, observe that f induces a Boolean algebra homomorphism $B(f)=B(G)\to B(H)$, where $B(G)$ and $B(H)$ are the respective Boolean algebras of supports: Define $B(f)\big(\mathrm{supp}(g)\big)=\mathrm{supp}\,\big(f(g)\big)$. The good definition results from the fact that f maps weak units on weak units and preserves the lattice operations: So, let $g,g'\in G$ such that $\mathrm{supp}(g)=\mathrm{supp}(g')$. Let u be a weak unit in G. The element $g''=\mathrm{pr}(u,g')$ is orthogonal to both g and g', and both $g+g''$ and $g'+g''$ are weak units. So since $\mathrm{supp}\,\big(f(g)+f(g'')\big)=\mathrm{supp}\,\big(f(g')+f(g'')\big)=I'$ (where I' is the Boolean space of H) and $f(g')\perp f(g'')$ we have that $\mathrm{supp}\,\big(f(g')\big)\subseteq\mathrm{supp}\,\big(f(g)\big)$. The proof of the other inclusion is analogous.

Now, if A and B are the respective MV-algebras constructed from G and H respectively, as above, define $\tilde{f}\colon A\to B$ by $\tilde{f}\big((g,\alpha)\big)=\big(f(g),B(f)(\alpha)\big)$. We shall proof that it is an MV-homomorphism: Let $(g,\alpha),(h,\beta)\in A$, call $\alpha' = I\setminus \operatorname{supp}(g)$ (where I is the Boolean space of G). Then

$$\begin{aligned}\tilde f(\neg(g,\alpha)) = \tilde f(-g,(I\setminus\alpha)\cap\alpha') &= (f(-g), B(f)((I\setminus\alpha)\cap\alpha'))\\ &= (-f(g),(B(f)(I)\setminus B(f)(\alpha))\cap B(f)(\alpha'))\\ &= (-f(g),(I'\setminus B(f)(\alpha))\cap B(f)(\alpha')).\end{aligned}$$

By calling $\alpha'' = I'\setminus \operatorname{supp}(f(g))$, we have also

$$\neg\tilde f((g,\alpha)) = (-f(g),(I'\setminus B(f)(\alpha))\cap\alpha'').$$

Since $\alpha'' = B(f)(\alpha')$ we have that $\tilde f$ preserves the operation $\neg$.

For $\oplus$, call $\gamma = I\setminus(\alpha\cup\beta)$, $g' = g|\gamma$, $h' = h|\gamma$, $\delta = \gamma\cap[\![g'\leqslant g'+h']\!]$ and $\eta = \neg[\![g'\leqslant g'+h']\!]$. We have

$$\begin{aligned}(g,\alpha)\oplus(h,\beta) &= ((g'+h')|\delta, \alpha\cup\beta\cup\eta),\\ \tilde f((g,\alpha)\oplus(h,\beta)) &= (f((g'+h')|\delta), B(f)(\alpha\cup\beta\cup\eta))\\ &= (f(g'|\delta)+f(h'|\delta), B(f)(\alpha\cup\beta\cup\eta))\end{aligned}$$

By the other side, calling $\mu = B(f)(\alpha)$, $\nu = B(f)(\beta)$, $\sigma = I'\setminus(\mu\cup\nu) = B(f)(\gamma)$, $\upsilon = \neg[\![f(g')\leqslant f(g')+f(h')]\!]$ (because f preserves the relation T), $g'' = f(g)|\sigma$, $h'' = f(h)|\sigma$, and $\tau = \sigma\cap[\![g''\leqslant g''+h'']\!]$, we have

$$\tilde f((g,\alpha))\oplus\tilde f((h,\beta)) = (f(g),\mu)\oplus(f(h),\nu) = ((f(g)+f(h))|\tau, \mu\cup\nu\cup\upsilon).$$

Since, for each $i\in I$, $g'(i)\leqslant g'(i)+h'(i)$ if and only if $f(g')(i)\leqslant f(g')(i)+f(h')(i)$ because of axiom C1 and the fact that f is an lc-homomorphism, we have that $\upsilon = B(f)(\eta)$, proving $\tilde f((g,\alpha)\oplus(h,\beta)) = \tilde f((g,\alpha))\oplus\tilde f((h,\beta))$.

Finally we show that the compositions of both functors are the identity:

Call LC and MV, the categories of projectable lc-groups with weak unit and projectable MV-algebras, respectively, $\Psi\colon \mathrm{MV}\to\mathrm{LC}$ and $\Phi\colon\mathrm{LC}\to\mathrm{MV}$ the above constructed functors.

Let $G\in\mathrm{LC}$, $\Phi(G) = \{(g,\alpha)\in G\times B(I)\mid \operatorname{supp}(g)\cap\alpha = \emptyset\}$ (as a set) and $\Psi(\Phi(G)) = \Phi(G)/\!\sim$ (as a set). Observe that $a = (g,\alpha)\sim(h,\beta) = b$ if and only if $g = h$: by taking $a' = (0,\beta\setminus\alpha)$ and $b' = (0,\alpha\setminus\beta)$, we have $a\oplus a' = b\oplus b'$, $a'\perp b'$, $a\perp a'$ and $b\perp b'$, implying $(g,\alpha)\sim(g,\beta)$. Suppose now $g\neq h$, then the set $[\![a=b]\!]\cup[\![a=0\ \&\ b=1]\!]\cup[\![a=1\ \&\ b=0]\!]$ is strictly contained in I, implying that (g,α) is not equivalent to (h,β). Now, for the operations, it is immediate for 0 and $-$. Let $g,h\in G$, we can choose, for their images in $\Phi(G)$, the elements $(g,\emptyset)$ and $(h,\emptyset)$ respectively. By calling $J = [\![(g,\emptyset)\oplus(h,\emptyset)<1]\!]$, we have, in $\Psi(\Phi(G))$, $g+h = (((g,\emptyset)\oplus(h,\emptyset))|J \cup ((g,\emptyset)*(h,\emptyset))|I\setminus J)/\sim$. Observe that $J = [\![g \leqslant g+h]\!]$ and then $(g,\emptyset)\oplus(h,\emptyset) = ((g+h)|J, I\setminus J)$. So, it holds $g+h = (g+h)|J \cup (((g,\emptyset)*(h,\emptyset))|I\setminus J)/\sim = (g+h)|J \cup (\neg(\neg(g,\emptyset)\oplus\neg(h,\emptyset))|I\setminus J)/\sim = (g+h)|J \cup (\neg((-g,\emptyset)\oplus(-h,\emptyset))|I\setminus J)/\sim = (g+h)|J \cup (\neg((-g-h,\emptyset))_{I\setminus J})/\sim$ because $[\![-g \leqslant -g-h]\!] = I\setminus J$. So, we can conclude (in $\Psi(\Phi(G))$), $g+h = (g+h)|J \cup (-(-g,h))|I\setminus J = g+h$ (in G). We have, proved, then, that $\Psi\circ\Phi = \mathrm{Id}_G$.

For the converse, let $A \in$ MV. In $\Psi(A)$ the elements of A which coincide modulo a Boolean element are identified. Let $a \in A$. By setting $\alpha = [\![a=1]\!]$, we have that, in $\Phi\circ\Psi(A)$ the element $(a/\sim, \alpha)$ corresponds to a (in A). So, it is immediate to verify that the application $a \rightarrow (a/\sim,\alpha)$ gives a bijection between A and $\Phi\circ\Psi(A)$ preserving the 0 and 1. For the negation, $[\![\neg a = 1]\!] = [\![a=0]\!] = I\setminus(\alpha\cup \mathrm{supp}(a/\sim))$ and call $\beta = I\setminus\mathrm{supp}(a/\sim)$. We have then $\neg(a/\sim,\alpha) = (-(a/\sim),(I\setminus\alpha)\cap\beta) = (\neg a/\sim, I\setminus(\alpha\cup\mathrm{supp}(a/\sim)))$ proving that the above defined map preserves also the negation.

Finally, for the MV sum, let $a,b \in A$, $\alpha = [\![a=1]\!]$ and $\beta = [\![b=1]\!]$. Define $\gamma = I\setminus(\alpha\cup\beta)$, $(a/\sim)' = (a/\sim)|\gamma = (a|\gamma)/\sim$, $(b/\sim)' = (b/\sim)|\gamma = (b|\gamma)/\sim$, $\delta = \gamma\cap[\![(a/\sim)' \leqslant (a/\sim)'+(b/\sim)']\!]$ and $\eta = \neg[\![(a/\sim)' \leqslant (a/\sim)'+(b/\sim)']\!]$. So, we can write $(a/\sim,\alpha)\oplus(b/\sim,\beta) = (((a/\sim)'+(b/\sim)')|\delta, \alpha\cup\beta\cup\eta)$. Call now $J = [\![a|\gamma\oplus b|\gamma < 1]\!]$. We have then $(a/\sim)'+(b/\sim)' = (a\oplus b)|J\cap\gamma \cup (a*b)|(I\setminus J)\cap\gamma$, which implies $(a/\sim,\alpha)\oplus(b/\sim,\beta) = (a\oplus b)|J\cap\delta\cup(a*b)|(I\setminus J)\cap\delta\cup\alpha\cup\beta\cup\eta$. It is easy to verify that $J=\delta$, implying $(a/\sim,\alpha)\oplus(b/\sim,\beta) = (a\oplus b)|\delta\cup\alpha\cup\beta\cup\eta = a\oplus b$ because $\alpha\cup\beta\cup\eta = [\![a\oplus b]\!] = 1$.

So we can state the

Theorem 4.1. *The categories LC and MV are equivalent.*
