# Some remarks on paracompactness of GO-spaces

by

W. Kulpa (Katowice).

Let $X = (X,<)$ be a linearly ordered set. A subset $C \subset X$ is said to be convex, whenever $a,b \in C$ and $a<b$ imply that $[a,b] \subset C$. A convex set $C \subset A$, $A \subset X$, is called a convexity-component of $A$, whenever $C' \cap C \neq \emptyset$ implies $C' \subset C$ for each convex set $C' \subset A$.

A linearly ordered topological space X is a triple $X = (X, <, \lambda(<))$ where $(X,<)$ is a linearly ordered set on which a topology is defined by the subbase of all sets $(\leftarrow, a), (b, \rightarrow)$ with $a,b \in X$.

A generalized ordered space X (abbreviated GO-space) is a triple $X = (X, <, \tau)$, where $\tau \supset \lambda(<)$ is a topology with a base consisting of convex subsets of X.

A continuous map $f: X \to M$ from a GO-space X is said to be convexity-paracompact (convexity-zerodimensional) iff each convexity component of $f^{-1}(m)$, $m \in M$, is paracompact (is a one-point set).

**Theorem 1.** If a GO-space X has a convexity-paracompact map into a metric space, then X is paracompact.

**Theorem 2.** If a GO-space X has a perfect map onto a Dieudonné complete space, then X is paracompact.

Theorem 1 strengthens a result of Faber [1] who has proved that each GO-space which has a convexity-zerodimensional map into a metric space must be paracompact. Theorem 2 is a strengthening of a result of Lutzer [4] who has proved that each Dieudonne complete GO-space is paracompact.

The above theorems one can obtain from the Pressing-Down Lemma and from the following results:

<u>Factorization Theorem [3].</u> Let $f: X \to M$ be a continuous map from a GO-space $X = (X, <, \tau)$ into a metric space $M$. Then there exists a metric GO-space $Z = (Z, \prec, \mathcal{T})$ and continuous maps $g: X \xrightarrow{\text{onto}} Z$, $h: Z \to M$ such that $f = h \circ g$ and $g(x) \preceq g(y)$ whenever $x \leq y$, for each $x, y \in X$.

<u>Lemma [illegible].</u> If a GO-space $X$ has a continuous map $f: X \to M$ into a space $M$ with a $G_\delta$-diagonal such that for each $m \in M$, $f^{-1}(m)$ is paracompact, then $X$ paracompact.

<u>Lemma [3].</u> If $f: S \to M$ is a continuous map from a stationary set $S \subset \kappa$, $\kappa = cf\kappa > \omega$, into a space $M$ with a $G_\delta$-diagonal, then there is an $\alpha < \kappa$ such that $f | S \cap [\alpha, \kappa)$ is constant.

The last Lemma generalizes a result of Lutzer [4] who has proved that if $f: S \to M$ is a continuous map of a stationary set $S \subset \kappa$, $\kappa = cf\kappa > \omega$, into a metric space $M$, then $card(f[S]) < \kappa$.

<u>Theorem [1].</u> A GO-space $X$ is not paracompact iff some closed subspace of $X$ is homeomorphic to a stationary set $S \subset \kappa$, $\kappa = cf\kappa > \omega$.
