## REGULARITY: A GENERALIZATION OF EQUICONTINUITY

SAROOP K. KAUL

Regina -

### 1. Single valued functions:

Let  $(X, Y)$  denote the set of all functions from a space  $X$  to a space  $Y$ . We say  $F \subseteq (X, Y)$  is regular at  $x \in X$  if given an open set  $U$  and a subset  $H \subset F$  such that  $\overline{H(x)} \subset U$ , where  $H(x) = \{f(x) : f \in H\}$ , there exists an open set  $V$  containing  $x$  such that  $H(V) \subset U$ , where  $H(V) = \bigcup \{H(z) : z \in V\}$ .  $F$  is said to be regular if it is regular at each point of  $X$ . For the definition of even continuity see [7].

Theorem (1.1): If  $Y$  is a regular space,  $F \subset (X, Y)$  and  $\overline{F(x)}$  is compact for each  $x \in X$ , then  $F$  is regular if and only if it is evenly continuous.

Thus, as a corollary to this, we have that in the Ascoli theorem in [4] one can replace even continuity by regularity.

Theorem (1.2): Let  $Y$  be a regular space,  $F \subset (X, Y)$  be regular, and  $\overline{F}$  be the pointwise closure of  $F$ . Then  $f \in \overline{F}$  implies  $f$  is continuous.

These and other results have been proved in [3].

### 2. Set valued functions:

Let us consider the set of all set valued functions  $\mathcal{f} = \mathcal{f}(X, Y)$ , from a space  $X$  to a space  $Y$ , where a set valued function  $f: X \rightarrow Y$  induces a single valued function  $\hat{f}: X \rightarrow 2^Y$ ,  $2^Y$  being the set of all closed non-empty subsets of  $Y$ . Given any topology  $t$  on  $2^Y$ , we say that  $f$  is  $t$ -continuous if  $\hat{f}$  is  $t$ -continuous; and also talk of the pointwise topology  $p_t$  and the compact open topology  $c_t$  on  $\mathcal{f}$  as those which make  $f \leftrightarrow \hat{f}$  a homeomorphism with the corresponding topologies on  $\hat{\mathcal{f}} = \{\hat{f} : f \in \mathcal{f}\} = (X, 2^Y)$ . Let  $\kappa$ ,  $\tau$ , and  $\nu$  denote the upper semi-finite, lower semi-finite and finite topologies on  $2^Y$  [9] respectively. It is interesting then that natural generalizations of regularity and even continuity give

results, similar to those in §1, for set valued functions. So let  $F \in \mathcal{F}$ .

Regularity:  $F$  is said to be regular at  $x \in X$  if given an open set  $U$  in  $Y$  and a subset  $H$  of  $F$  such that  $\overline{H(x)} \subset U$ , where  $H(x) = \bigcup \{f(x) : f \in H\}$ , there exists an open set  $V$  containing  $x$  such that  $H(V) \subset U$ , where  $H(V) = \bigcup \{H(x) : x \in V\}$ .

Even Continuity:  $F$  is said to be evenly continuous at  $x \in X$  if given any  $y \in Y$  and a closed neighbourhood  $V$  of  $y$  there exists an open neighbourhood  $W$  of  $y$  and an open neighbourhood  $U$  of  $x$ , such that if  $g \in F$  and  $g(y) \cap W \neq \emptyset$  then  $U \subset \tilde{g}[V] = \{z \in X : g(z) \cap V \neq \emptyset\}$ ;  $F$  is said to be evenly continuous if it is evenly continuous at each point of  $X$ .

Let  $S = \{f \in \mathcal{F} : f(x) \text{ is compact for each } x \in X\} = S(X, Y)$ .

Theorem (2.1): Let  $Y$  be a normal space. If  $F \in S$  is regular,  $\overline{F(x)}$  is compact for each  $x \in X$ , and  $F$  is a closed subset of  $(S, c_\kappa)$ , then  $(F, c_\kappa)$  is compact.

Theorem (2.2): Let  $Y$  be a regular space. If  $F \in S$  is evenly continuous,  $\overline{F(x)}$  is compact for each  $x \in X$  and  $F$  is closed in  $(S, c_\tau)$ , then  $(F, c_\tau)$  is compact.

Theorem (2.3): Let  $Y$  be a regular space,  $X$  be locally compact. If  $F$  is a closed subset of  $(S, c_\nu)$  then  $(F, c_\nu)$  is compact if and only if (1)  $F$  is regular, (2)  $F$  is evenly continuous, and (3)  $\overline{F(x)}$  is compact for each  $x \in X$ .

Remark. For single valued  $F$ , under the hypothesis of the theorem, even continuity and regularity are the same. Hence this theorem gives a complete generalization of the Ascoli theorem [7, theorem 21, p. 236], for  $\nu$ -continuous compact valued functions.

Theorem (2.4): Let  $Y$  be a regular space, and  $F \in S$  be a set of  $t$ -continuous functions in  $S$  for a topology  $t$  on  $2^Y$ . If  $f \in \text{cl}_{P_t}(F)$  in  $S$ , then  $f$  is  $t$ -continuous for  $t = \kappa$  or  $t = \tau$  provided  $F$  is respectively regular or evenly continuous.

3. Following Fuller's result [2], for local compactness in single valued function spaces, we have the following theorems for set valued functions. Let  $S = S(X, Y)$  be as in §2 above.

Theorem (3.1): Let  $X$  be a compact  $T_2$ -space and  $Y$  be a locally compact  $T_2$ -space. If  $F \in S$  is regular and evenly continuous then  $\bar{F}$  the closure of  $F$  with respect to  $p_v$  in  $S$  is locally compact.

Theorem (3.2): Let  $X$  be a compact  $T_2$ -space and  $Y$  be a locally compact normal  $T_2$ -space. If  $F \in S$  is regular then  $\bar{F}$  the closure of  $F$  in  $(S, p_v)$  is locally compact.

#### 4. Regularity:

Let  $\mathcal{f} = \mathcal{f}(X, Y)$  be the set of all set valued functions from a space  $X$  to a space  $Y$  as in §2. Given any  $f \in \mathcal{f}$ , by the graph  $G(f)$  of  $f$  is meant the subset  $\{(x, y) : y \in f(x), x \in X\}$  of  $X \times Y$ . For any  $F \in \mathcal{f}$  we define the set valued function  $\pi_F: X \rightarrow Y$  given by  $\pi_F(x) = \overline{F(x)}$ ,  $x \in X$ . From a theorem of Billera [1] we have immediately,

Theorem (4.1): Let  $Y$  be a compact  $T_2$ -space. Then  $F \in \mathcal{f}(X, Y)$  is regular if and only if for any subset  $H$  of  $F$ ,  $\pi_H$  has a closed graph in  $X \times Y$ .

Again, given  $f \in \mathcal{f}$  one can write formally  $f^*(y) = \{x : y \in f(x)\}$ . If  $f^*$  is a set valued function from  $Y$  to  $X$  then  $(x, y) \rightarrow (y, x)$  maps  $G(f)$  onto  $G(f^*)$  in 1-1 manner. If  $F \in \mathcal{f}$  set  $F^* = \{f^* : f \in F\}$ .

Theorem (4.2): Let  $X$  and  $Y$  be compact  $T_2$ -spaces. If  $F \in \mathcal{f}(X, Y)$  and  $F^* = \mathcal{f}(Y, X)$  mapping  $*$ :  $(F, p_v) \rightarrow (F^*, p_v)$  given by  $*(f) = f^*$  is a homeomorphism.

Remark 1. In the above theorem  $F$  and  $F^*$  regular implies that each is a set of u.s.c., functions but not necessarily l.s.c.

Remark 2. Let  $X$  and  $Y$  be compact  $T_2$ -spaces and  $SO(X, Y)$  be the set of all open and continuous functions from  $X$  onto  $Y$ .

Then the set  $D(Y, X) = \{f^* = f^{-1} : f \in SO(X, Y)\}$  is the set of all  $\nu$ -continuous, open "decompositions" from  $Y$  onto  $X$ , where  $f^*$  is a decomposition means that for  $y_1, y_2 \in Y$  and  $y_1 \neq y_2$ ,  $f^*(y_1) \cap f^*(y_2) = \emptyset$ , and onto means that  $f^*(Y) = X$ . For single valued functions let  $c$  and  $p$  denote the compact-open and the pointwise topologies respectively on the function space.

Theorem (4.3): Let  $F \subset SO(X, Y)$  and  $(F, c)$  be compact. If for any net  $\{f_\alpha\}$  in  $F$ ,  $\bigcup\{\limsup f_\alpha(y) : y \in Y\} = X$ , then  
 \*:  $(F, c) \rightarrow (F^*, c_\nu)$  is a homeomorphism.

Theorem (4.4): Let  $F \subset D(Y, X)$  and  $(F, c_\nu)$  be compact. Then  
 \*:  $(F, c_\nu) \rightarrow (F^*, c)$  is a homeomorphism.

Corollary to theorem (4.3): Suppose  $X$  and  $Y$  are compact  $T_2$ -spaces and  $\{f_n\}$  is a sequence of monotone open mapping from  $X$  onto  $Y$  converging in  $c$  to an open mapping  $f$  from  $X$  onto  $Y$ . If  $\bigcup_{i \rightarrow \infty} \{\limsup_{n_i} f_{n_i}^{-1}(y) : y \in Y\} = X$  for each subsequence  $\{f_{n_i}\}$  of  $\{f_n\}$ , then  $f$  is monotone.

Corollary to theorem (4.4): Suppose  $F$  is a set of monotone open mappings in  $SO(X, Y)$  where  $X$  and  $Y$  are compact  $T_2$ -spaces. If  $F^*$  has a compact closure in  $(D(Y, X), c_\nu)$  then  $\bar{F}$  the closure of  $F$  in  $(SO(X, Y), c)$  is compact and  $f \in \bar{F}$  implies that  $f$  is monotone.

## 5. Regularity and Even Continuity:

Theorem (5.1): Let  $F \subset S(X, Y)$  be regular and evenly continuous, let  $X$  be a compact  $T_2$ -space and  $Y$  be a regular  $T_2$ -space. If  $\{f_\alpha\}$  is a net in  $F$  converging to  $f \in F$  with respect to  $p_\nu$ , then  $\{G(f_\alpha)\}$  converges to  $G(f)$  in  $(2^{X \times Y}, \nu)$ .

Theorem (5.2): Let  $Y$  be a regular  $T_2$ -space and  $F \subset S(X, Y)$  be regular and evenly continuous. Let  $\{f_\alpha\}$  be a net in  $F$  and  $\{G(f_\alpha)\}$  converge to a compact subset  $A \in 2^{X \times Y}$  with respect to  $\nu$  on  $2^{X \times Y}$ . Then  $A = G(f)$  for some  $f \in S(X, Y)$  and  $\{f_\alpha\}$  converges to  $f$  with respect to  $p_\nu$ .
